
Procedure

PRESS the F-PLN key on the MCDU.
SELECT the VERT REV page at the revised waypoint.
WRITE the speed constraint value into the scratchpad and ENTER it in 3L.
INSERT the constraint using the appropriate *CLB or DES* prompt when displayed. If CLB and DES are not displayed, insertion occurs when the value is entered in 3L.

The system displays the climb (CLB) or the descent (DES) prompt at [6L] or [6R] when the predictions are not yet available or when the waypoint is part of the cruise phase as originally defined.

When predictions are not yet available, the constraints are displayed on the F-PLN A page in magenta.

When predictions are available, the speed constraint is highlighted by a star (*).

** If the predicted speed matches the constraint, the star is magenta.*

** If the prediction is that the aircraft will miss the speed constraint, the star is amber.*

If a speed constraint cannot be met (by more than 10 kt), the FMGS generates the message "SPD ERROR AT WPT XX".

A speed constraint may be assigned to any waypoint in the climb or the descent phase except the FROM, origin, or destination waypoints, and any pseudo waypoint.

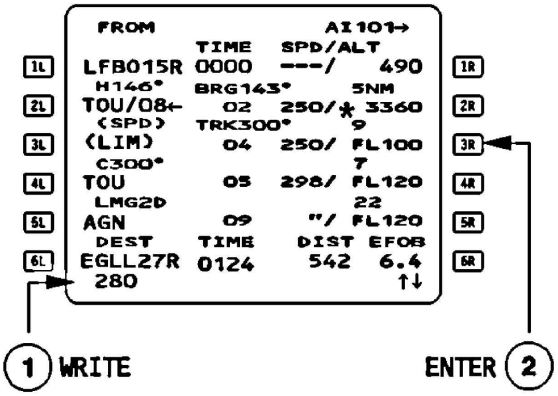
When a speed constraint is assigned to a waypoint, the constraint will limit the managed speed target as follows:

- *In takeoff or climb phase until you pass the constrained waypoint.*
- *In descent an approach phase, after passing the constrained waypoint.*

Speed constraints are observed by the FMGS when NAV mode and speed managed are active.

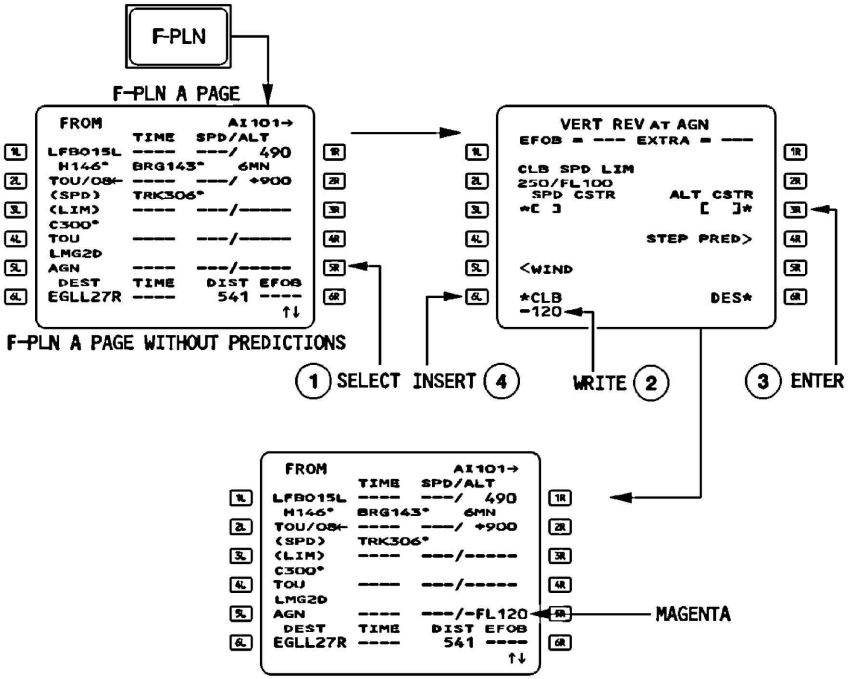
ENTERING A SPEED CONSTRAINT THROUGH F-PLN A PAGE

You may also enter a speed constraint through the F-PLN A page.



Note: *You may delete the constraint using the clear key on the relevant right hand key. However if there is an altitude constraint assigned at that point, the clear action deletes it too.*

ENTERING AN ALTITUDE CONSTRAINT



Procedure

PRESS the F-PLN key on the MCDU.
SELECT the “VERT REV”page at the revised waypoint.
WRITE an altitude constraint in the scratchpad and ENTER it in 3R.
INSERT the constraint using *CLB or DES* prompt when it is displayed. Otherwise the value is inserted when it is entered in 3R field.

*The system displays the *CLB or DES* prompt, when the predictions are not yet available, or when the waypoint is part of the cruise phase as originally defined.*

Note: In case of QFE operations, the altitude constraints must be converted and entered as an altitude in feet.

You or the database may assign an altitude constraint to any waypoint in the climb or descent phases except the FROM, origin, or destination waypoints, or any pseudo waypoint.

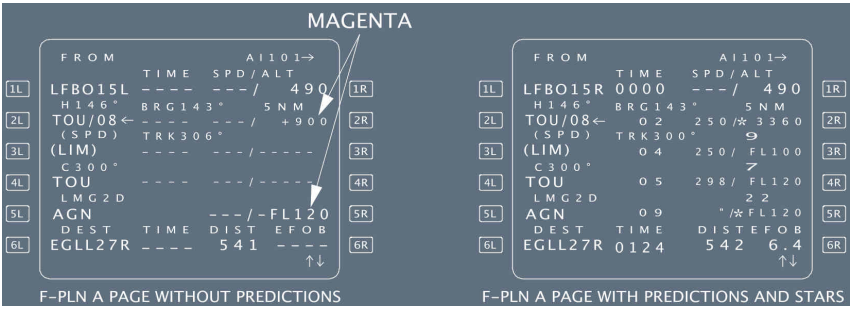
An altitude constraint may be defined as an “at”, an “at or above”, or an “at or below” constraint. In certain procedures, the database may define an altitude constraint as a window in which the aircraft should fly.

Enter “AT” constraints with no sign.
Enter “AT or ABOVE” constraints preceded by a + sign (+FL 130, for example).
Enter “AT or BELOW” constraints preceded by a – sign (-15 000, for example).
enter four or five-digit number when entering altitude. Include the lead zero (0 500 ft , for example).

For flight level, enter a two- or three-digit number, with or without the letters “FL”. The lead zero is optional. (Examples : +FL 120 or + 120 ; -FL 090 or -90 or - 090)

Enter the altitude value as either altitude or flight level; the MCDU displays the selected value as an “ALT”or “FL,” as appropriate for the transition altitude.

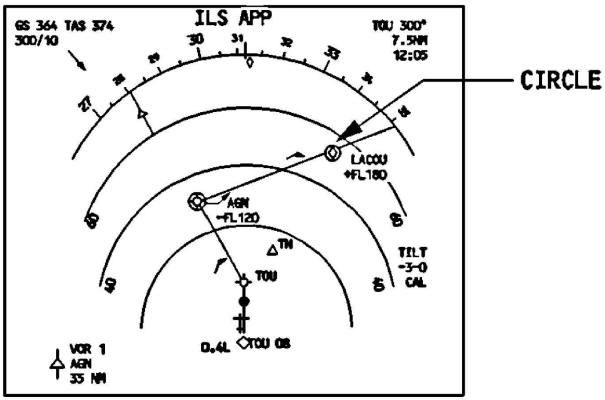
The constraint must be higher than the thrust reduction altitude and lower than the cruise flight level.
Once inserted in the flight plan, the altitude constraint (ALT CSTR) is displayed in magenta as long as predictions are not available.
When predictions are available, the altitude constraints are replaced by the predicted altitude at relevant waypoints highlighted by a star.
** If the predicted altitude matches the constraint the star is magenta. If the predicted altitude is missed (by more than 250 ft), the star is amber.*



The vertical revision page displays “ALT ERROR”, along with the difference between the constraint and the predicted altitude at the revised waypoint.

ND Display

An altitude-constrained waypoint is marked by a circle (○) on the navigation display.
This circle is white when the guidance does not take the altitude constraint into account. It is magenta if the guidance system takes the altitude constraint into account and predicts that it will be matched.
It is amber if the guidance system takes the altitude constraint into account and predicts that it will not be matched.

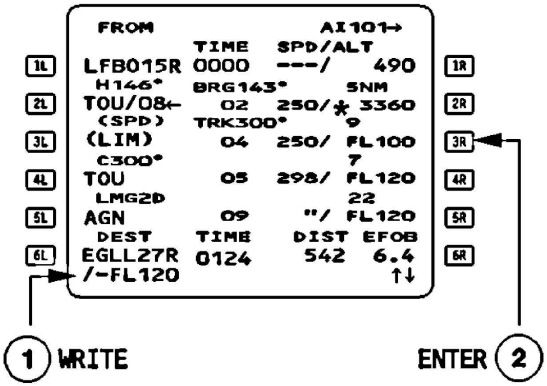


The aircraft should be at or below FL 120 at AGN and above FL 180 at LACOU.

Entering an Altitude Constraint Through F-PLN A Page

The pilot may also enter an altitude constraint directly through the F-PLN A page.

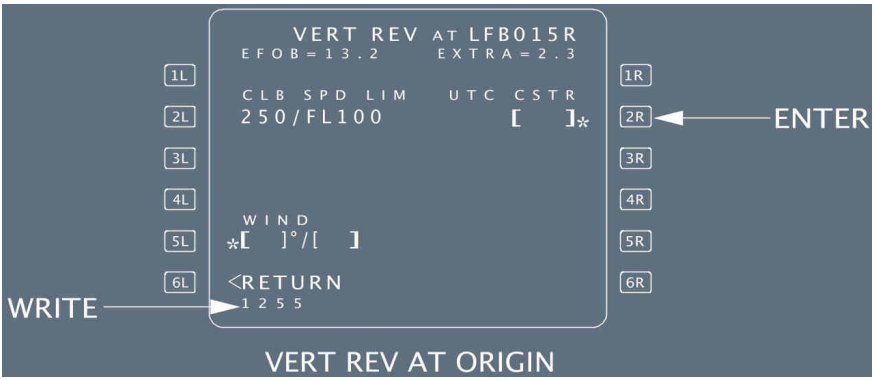
When entering the value into the scratchpad do not forget the slash e.g. /- 120 or /-FL 120. If the slash is omitted the value will be considered as a speed constraint if it is within the range value.



Use CLR to delete them directly from the flight plan page, as well. However, if there is also a speed constraint assigned at that waypoint, the clear action deletes it too.

ENTERING AN ESTIMATED TIME OF TAKEOFF (ETT)

The estimated takeoff time (ETT) is a time entered during preflight at the origin airport. The computer then uses this time as the start time for predictions. The system accepts it during the preflight phase if the ETT is later than the time at which you enter it.



Procedure

PRESS the F-PLN key

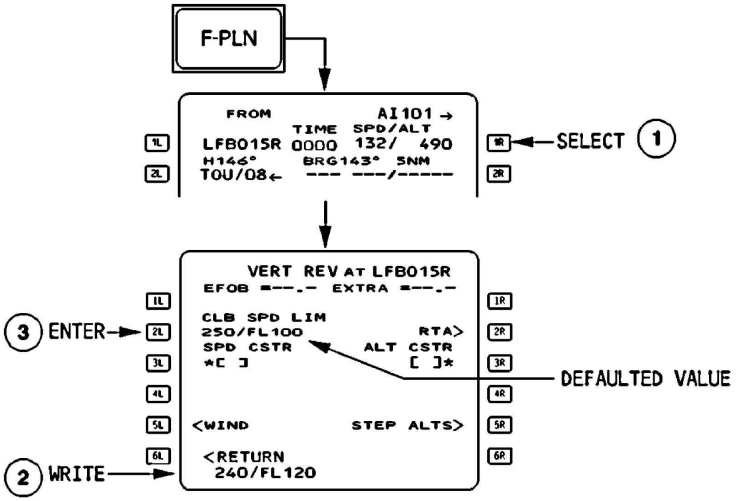
SELECT the VERT REV page at departure.
WRITE the estimated takeoff time into the scratchpad and ENTER it in 2R.

The display reverts automatically to F-PLN A page.
If the aircraft has not taken off by the time entered as the estimated takeoff time, the MCDU displays the "CLK IS TAKE OFF TIME" message, meaning that the system will replace your estimated takeoff time with the actual time.
When beginning the takeoff roll, the system automatically adopts that clock time as the takeoff time.
If the origin airport is changed, or the clock time is invalid, the system automatically deletes the estimated takeoff time.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

VERTICAL FLIGHT PLAN

ENTERING/MODIFYING A SPEED LIMIT



PRESS the F-PLN key on the MCDU.
SELECT VERTICAL REVISION at the FROM waypoint.
WRITE a new speed limit/altitude and ENTER.

The crew can insert one climb speed limit and one descent speed limit into the vertical flight plan, or modify or clear the limits that are already in it.

The speed limit is defined by a speed and an altitude (for example, 230/9 000), which means that the managed speed target will be limited by the speed limit when the aircraft flies below the specified altitude.

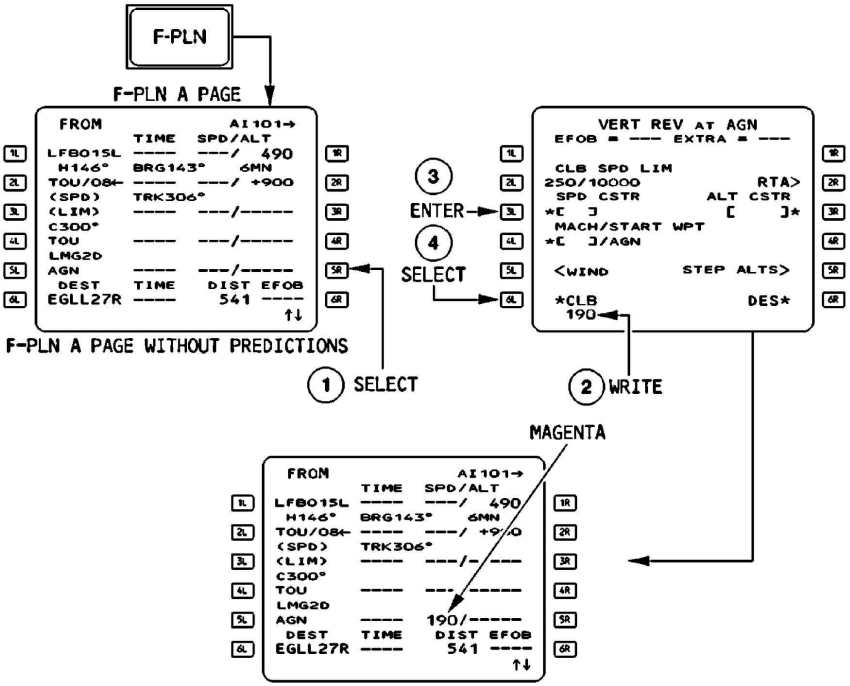
In both climb and descent, 250 kt at 10 000 ft is the default speed limit in the vertical flight plan.

The vertical revision page presents the climb speed (CLB SPD) limit if the revised waypoint is between departure and top of descent.

The vertical revision page shows the descent speed (DES SPD) limit, if the revised waypoint is between top of descent and destination.

It can be deleted by a clear action, the field reverts to brackets. It can also be cleared directly on the F-PLN A page by clearing the SPD LIM pseudo-waypoint.

ENTERING A SPEED CONSTRAINT



Procedure

PRESS the F-PLN key on the MCDU.
SELECT the VERT REV page at the revised waypoint.
WRITE the speed constraint value into the scratchpad and ENTER it in 3L.

INSERT the constraint using the appropriate *CLB or DES* prompt when displayed. If CLB and DES are not displayed, insertion occurs when the value is entered in 3L.

The system displays the climb (CLB) or the descent (DES) prompt at [6L] or [6R] when the predictions are not yet available or when the waypoint is part of the cruise phase as originally defined.

When predictions are not yet available, the constraints are displayed on the F-PLN A page in magenta.

When predictions are available, the speed constraint is highlighted by a star (*).

** If the predicted speed matches the constraint, the star is magenta.*

** If the prediction is that the aircraft will miss the speed constraint, the star is amber.*

If a speed constraint cannot be met (by more than 10 kt), the FMGS generates the message "SPD ERROR AT WPT XX".

A speed constraint may be assigned to any waypoint in the climb or the descent phase except the FROM, origin, or destination waypoints, and any pseudo waypoint.

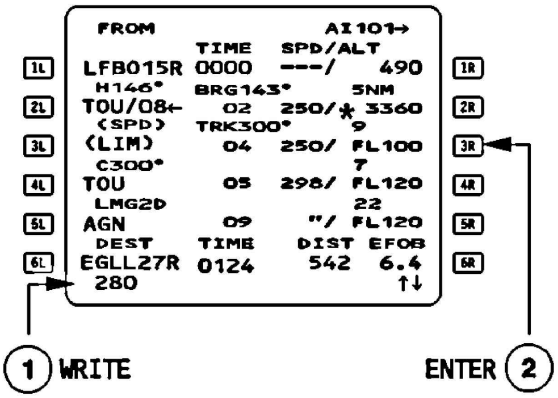
When a speed constraint is assigned to a waypoint, the constraint will limit the managed speed target as follows:

- *In takeoff or climb phase until you pass the constrained waypoint.*
- *In descent an approach phase, after passing the constrained waypoint.*

Speed constraints are observed by the FMGS when NAV mode and speed managed are active.

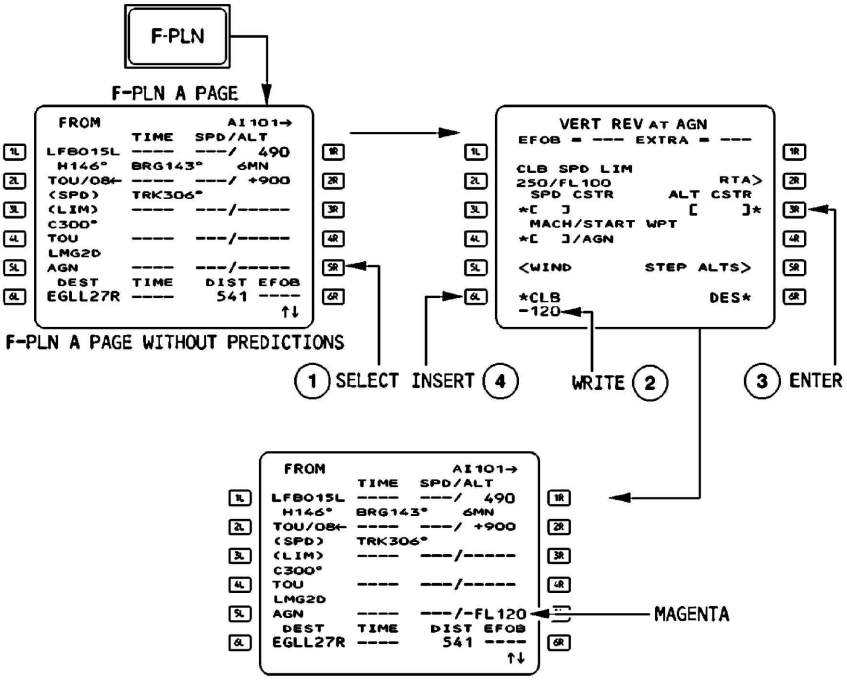
ENTERING A SPEED CONSTRAINT THROUGH F-PLN A PAGE

You may also enter a speed constraint through the F-PLN A page.



Note: You may delete the constraint using the clear key on the relevant right hand key. However if there is an altitude constraint assigned at that point, the clear action deletes it too.

ENTERING AN ALTITUDE CONSTRAINT



Procedure

PRESS the F-PLN key on the MCDU.
SELECT the “VERT REV”page at the revised waypoint.
WRITE an altitude constraint in the scratchpad and ENTER it in 3R.
INSERT the constraint using *CLB or DES* prompt when it is displayed. Otherwise the value is inserted when it is entered in 3R field.

*The system displays the *CLB or DES* prompt, when the predictions are not yet available, or when the waypoint is part of the cruise phase as originally defined.*

Note: In case of QFE operations, the altitude constraints must be converted and entered as an altitude in feet.

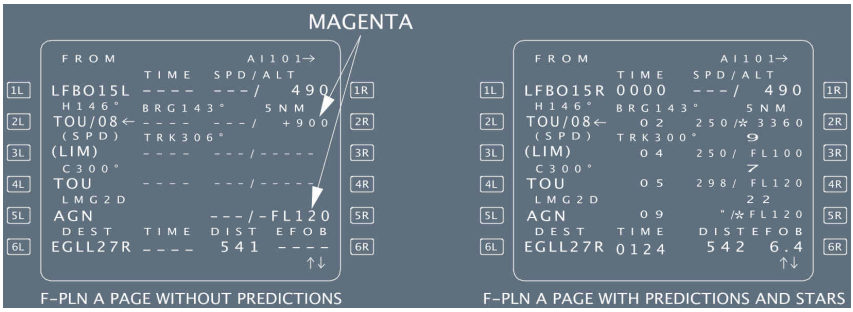
You or the database may assign an altitude constraint to any waypoint in the climb or descent phases except the FROM, origin, or destination waypoints, or any pseudo waypoint.
An altitude constraint may be defined as an “at”, an “at or above”, or an “at or below” constraint. In certain procedures, the database may define an altitude constraint as a window in which the aircraft should fly.

Enter “AT” constraints with no sign.
Enter “AT or ABOVE” constraints preceded by a + sign (+FL 130, for example).
Enter “AT or BELOW” constraints preceded by a – sign (-15 000, for example).
enter four or five-digit number when entering altitude. Include the lead zero (0 500 ft , for example).

For flight level, enter a two- or three-digit number, with or without the letters “FL”. The lead zero is optional. (Examples : +FL 120 or + 120 ; -FL 090 or -90 or - 090)

Enter the altitude value as either altitude or flight level ; the MCDU displays the selected value as an “ALT”or “FL,” as appropriate for the transition altitude.

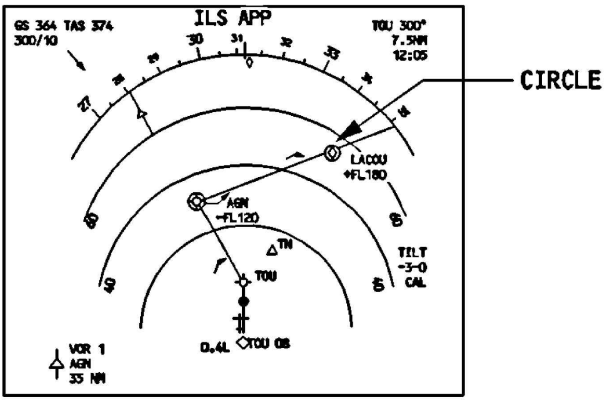
The constraint must be higher than the thrust reduction altitude and lower than the cruise flight level.
Once inserted in the flight plan, the altitude constraint (ALT CSTR) is displayed in magenta as long as predictions are not available.
When predictions are available, the altitude constraints are replaced by the predicted altitude at relevant waypoints highlighted by a star.
** If the predicted altitude matches the constraint the star is magenta. If the predicted altitude is missed (by more than 250 ft), the star is amber.*



The vertical revision page displays “ALT ERROR”, along with the difference between the constraint and the predicted altitude at the revised waypoint.

ND Display

An altitude-constrained waypoint is marked by a circle (◯) on the navigation display.
This circle is white when the guidance does not take the altitude constraint into account. It is magenta if the guidance system takes the altitude constraint into account and predicts that it will be matched.
It is amber if the guidance system takes the altitude constraint into account and predicts that it will not be matched.

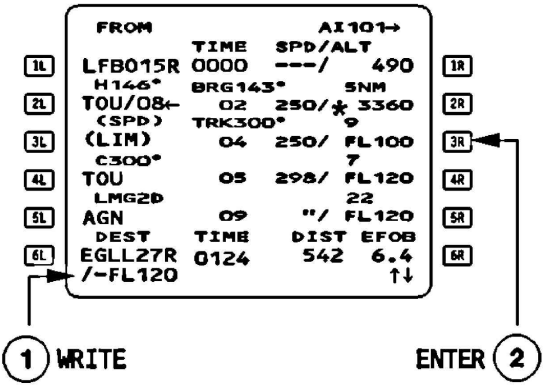


The aircraft should be at or below FL 120 at AGN and above FL 180 at LACOU.

Entering an Altitude Constraint Through F-PLN A Page

The pilot may also enter an altitude constraint directly through the F-PLN A page.

When entering the value into the scratchpad do not forget the slash e.g. /- 120 or /-FL 120. If the slash is omitted the value will be considered as a speed constraint if it is within the range value.



Use CLR to delete them directly from the flight plan page, as well. However, if there is also a speed constraint assigned at that waypoint, the clear action deletes it too.

ENTERING AN ESTIMATED TIME OF TAKEOFF (ETT)

In Preflight Phase:

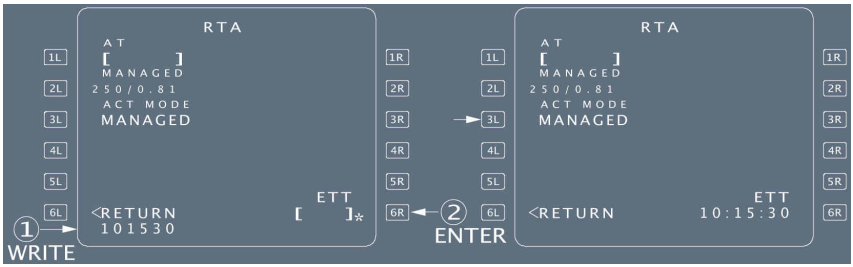
SELECT the SEC F-PLN key on the MCDU.
SELECT a VERT REV at any waypoint.
SELECT the Required Time of Arrival (RTA) prompt (2R).

The MCDU displays the RTA page.

ENTER the Estimated Takeoff Time in the [6R] field.

The format is HHMMSS (entry of seconds is not mandatory).

ENTER it in the 6R field

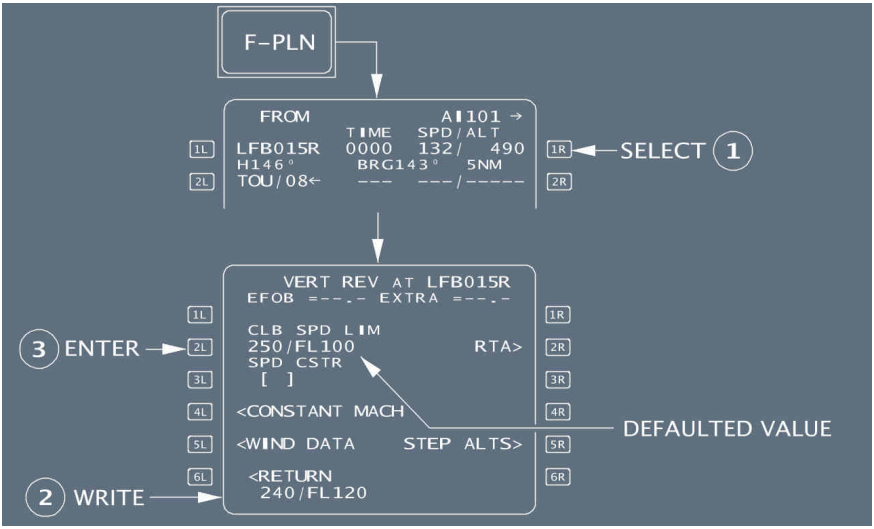


If the aircraft has not taken off by the time entered as estimated takeoff time, the MCDU displays the "CLK IS TAKE OFF TIME" message, meaning that the system will replace your estimated takeoff time with the actual time.
When beginning the takeoff roll, the system automatically adopts that clock time as the takeoff time.
If the origin airport is changed, or the clock time is invalid, the system automatically deletes the estimated takeoff time.

Applicable to: B-HSQ, B-HSR

VERTICAL FLIGHT PLAN

ENTERING/MODIFYING A SPEED LIMIT



PRESS the F-PLN key on the MCDU.
SELECT VERTICAL REVISION at the FROM waypoint.
WRITE a new speed limit/altitude and ENTER.

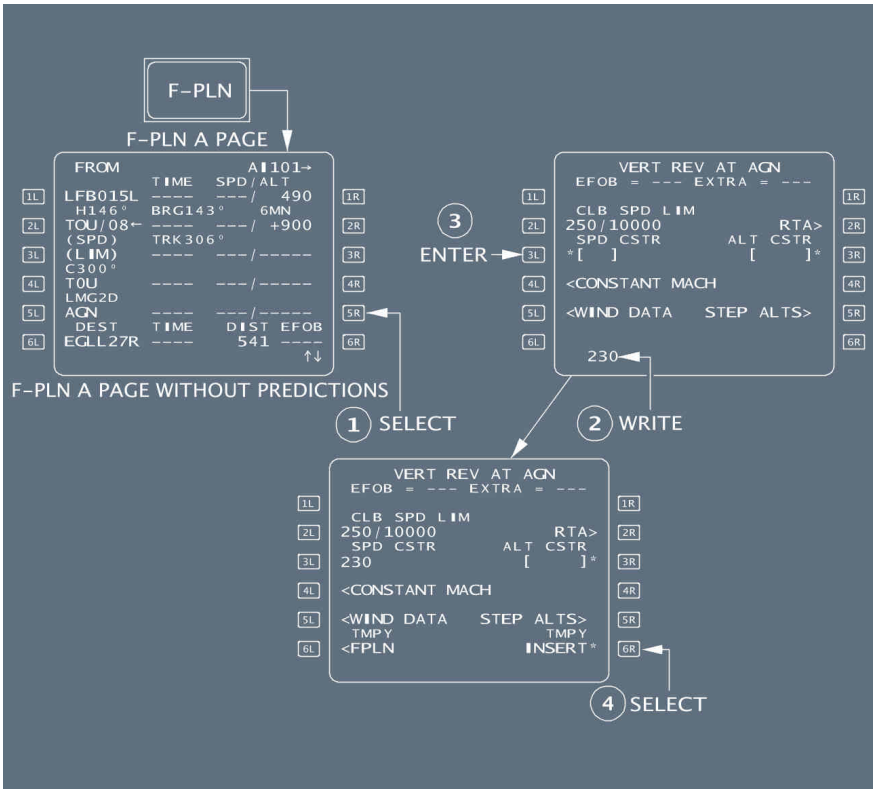
The crew can insert one climb speed limit and one descent speed limit into the vertical flight plan, or modify or clear the limits that are already in it.
The speed limit is defined by a speed and an altitude (for example, 230/9 000), which means that the managed speed target will be limited by the speed limit when the aircraft flies below the specified altitude.

In both climb and descent, 250 kt at 10 000 ft is the default speed limit in the vertical flight plan.
The vertical revision page presents the climb speed (CLB SPD) limit if the revised waypoint is between departure and top of descent.
The vertical revision page shows the descent speed (DES SPD) limit, if the revised waypoint is between top of descent and destination.
It can be deleted by a clear action, the field reverts to brackets. It can also be cleared directly on the F-PLN A page by clearing the SPD LIM pseudo-waypoint.

CHECK and INSERT the TMPY F-PLN or continue with next revision.

Note: The speed limit cannot be cleared in the temporary flight plan. If the crew inadvertly tries to clear the SPD LIM in the TMPY F-PLN, the message "NOT ALLOWED" is displayed in the scratchpad.

ENTERING A SPEED CONSTRAINT



Procedure

PRESS the F-PLN key on the MCDU.
SELECT the VERT REV page at the revised waypoint.
WRITE the speed constraint value into the scratchpad and ENTER it in 3L.
CHECK and INSERT the TMPY F-PLN or continue with next revision.

Note: *A speed constraint can also be entered directly on F-PLN page, without using VERT REV page.*

When predictions are not yet available, the constraints are displayed on the F-PLN A page in magenta.

When predictions are available, the speed constraint is highlighted by a star (*).
** If the predicted speed matches the constraint, the star is magenta.*
** If the prediction is that the aircraft will miss the speed constraint, the star is amber.*
If a speed constraint cannot be met (by more than 10 kt), the FMGS generates the message "SPD ERROR AT WPT XX".

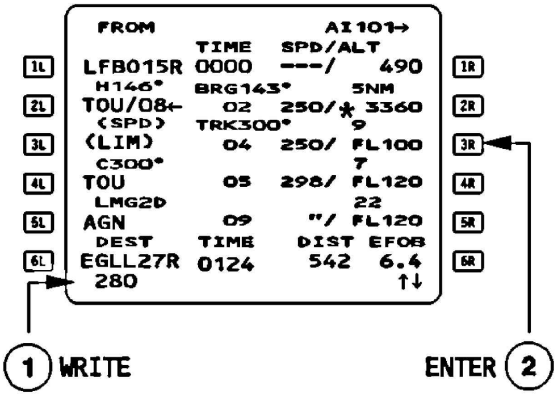
A speed constraint may be assigned to any waypoint in the climb or the descent phase except the FROM, origin, or destination waypoints, and any pseudo waypoint.

When a speed constraint is assigned to a waypoint, the constraint will limit the managed speed target as follows:
- *In takeoff or climb phase until you pass the constrained waypoint.*
- *In descent an approach phase, after passing the constrained waypoint.*

Speed constraints are observed by the FMGS when NAV mode and speed managed are active.

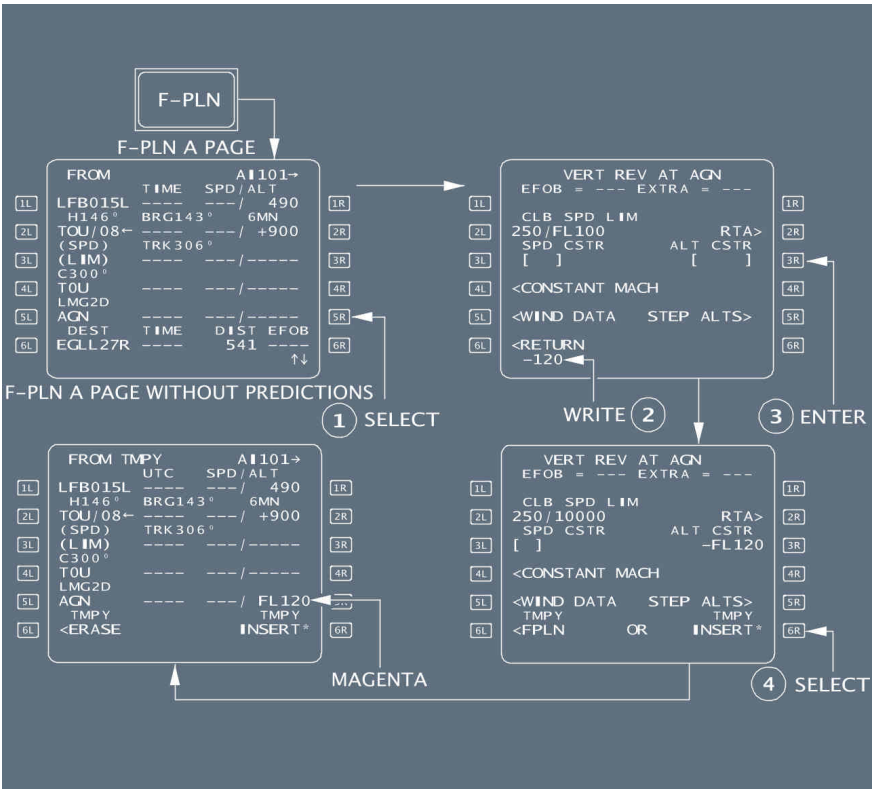
ENTERING A SPEED CONSTRAINT THROUGH F-PLN A PAGE

You may also enter a speed constraint through the F-PLN A page.



Note: *You may delete the constraint using the clear key on the relevant right hand key. However if there is an altitude constraint assigned at that point, the clear action deletes it too.*

ENTERING AN ALTITUDE CONSTRAINT



Procedure

PRESS the F-PLN key on the MCDU.
SELECT the "VERT REV"page at the revised waypoint.
WRITE an altitude constraint in the scratchpad and ENTER it in 3R.
If ← CLB and DES →prompt are displayed, SELECT the type of constraint.
The system displays the ← CLB or DES →prompt, when the predictions are not yet available, or when the waypoint is part of the cruise phase as originally defined.
CHECK and INSERT the TMPY F-PLN or continue with next revision

Note: *1. In case of QFE operations, the altitude constraints defined in heights (QFE) must be converted and entered in the FMS as altitudes (QNH).*
2. An altitude constraint can also be entered directly on F-PLN page, without using VERT REV page.

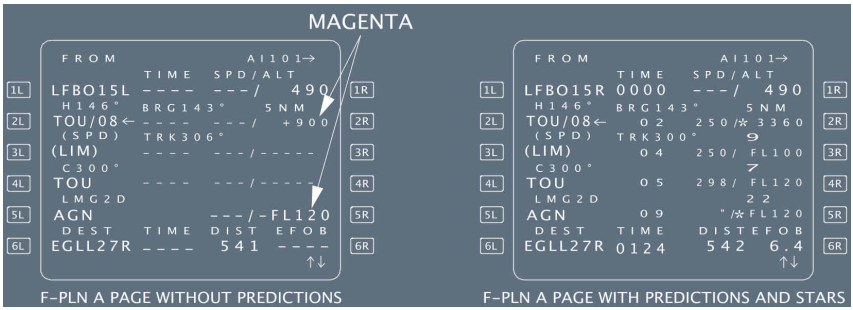
You or the database may assign an altitude constraint to any waypoint in the climb or descent phases except the FROM, origin, or destination waypoints, or any pseudo waypoint.
An altitude constraint may be defined as an “at”, an “at or above”, or an “at or below” constraint. In certain procedures, the database may define an altitude constraint as a window in which the aircraft should fly.

Enter “AT” constraints with no sign.
Enter “AT or ABOVE” constraints preceded by a + sign (+FL 130, for example).
Enter “AT or BELOW” constraints preceded by a – sign (-15 000, for example).
enter four or five-digit number when entering altitude. Include the lead zero (0 500 ft , for example).

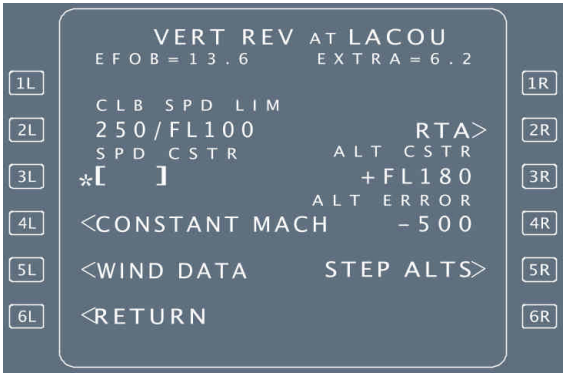
For flight level, enter a two- or three-digit number, with or without the letters “FL”. The lead zero is optional. (Examples : +FL 120 or + 120 ; -FL 090 or -90 or - 090)

Enter the altitude value as either altitude or flight level ; the MCDU displays the selected value as an “ALT”or “FL,” as appropriate for the transition altitude.

The constraint must be higher than the thrust reduction altitude and lower than the cruise flight level.
Once inserted in the flight plan, the altitude constraint (ALT CSTR) is displayed in magenta as long as predictions are not available.
When predictions are available, the altitude constraints are replaced by the predicted altitude at relevant waypoints highlighted by a star.
** If the predicted altitude matches the constraint the star is magenta. If the predicted altitude is missed (by more than 250 ft), the star is amber.*

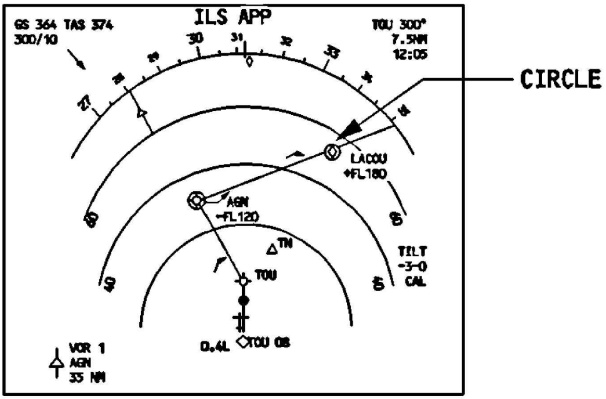


The vertical revision page displays “ALT ERROR”, along with the difference between the constraint and the predicted altitude at the revised waypoint.



ND Display

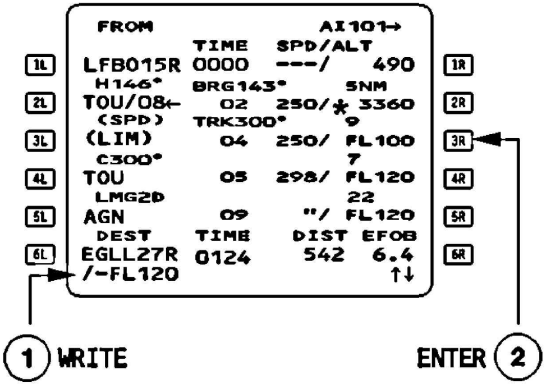
An altitude-constrained waypoint is marked by a circle (◯) on the navigation display.
This circle is white when the guidance does not take the altitude constraint into account. It is magenta if the guidance system takes the altitude constraint into account and predicts that it will be matched.
It is amber if the guidance system takes the altitude constraint into account and predicts that it will not be matched.



The aircraft should be at or below FL 120 at AGN and above FL 180 at LACOU.

Entering an Altitude Constraint Through F-PLN A Page

The pilot may also enter an altitude constraint directly through the F-PLN A page.
When entering the value into the scratchpad do not forget the slash e.g. /- 120 or /-FL 120.
If the slash is omitted the value will be considered as a speed constraint if it is within the range value.

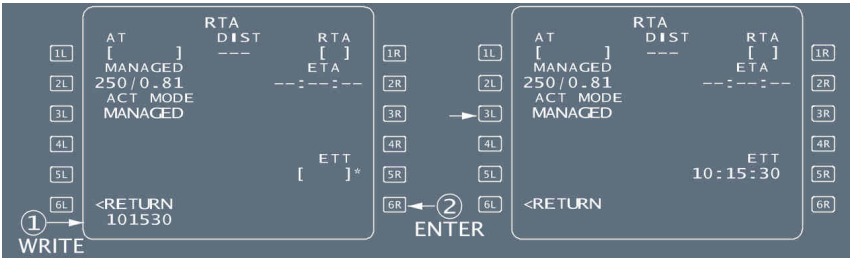


Use CLR to delete them directly from the flight plan page, as well. However, if there is also a speed constraint assigned at that waypoint, the clear action deletes it too.

ENTERING AN ESTIMATED TAKEOFF TIME (ETT)

In Preflight Phase:

SELECT the SEC F-PLN key on the MCDU.
SELECT a VERT REV at any waypoint.
SELECT the Required Time of Arrival (RTA) prompt (2R).
The MCDU displays the RTA page.
ENTER the Estimated Takeoff Time in the [5R] field.
The format is HHMMSS (entry of seconds is not mandatory).



If the aircraft has not taken off by the time entered as estimated takeoff time, the MCDU displays the “CLK IS TAKE OFF TIME” message, meaning that the system will replace your estimated takeoff time with the actual time.
When beginning the takeoff roll, the system automatically adopts that clock time as the takeoff time.
If the origin airport is changed, or the clock time is invalid, the system automatically deletes the estimated takeoff time.

Applicable to: ALL

FLIGHT PLAN CHECK

CHECK the EOSID on the ND plan mode (yellow line).

Note: *If the details of the EOSID require review, select the EOSID as a TMPY F-PLN and review it as TMPY. Then ERASE it.*

Applicable to: ALL

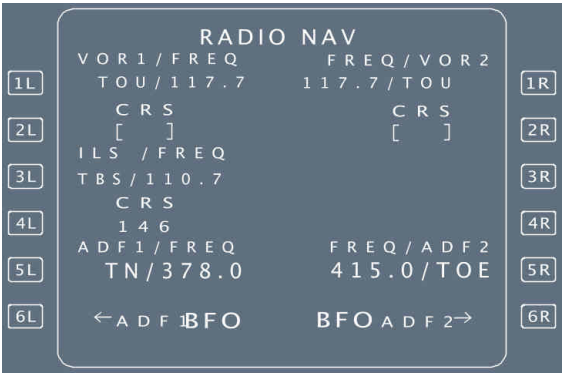
SECONDARY F-PLN

For details : *Refer to DSC-22_20-60-50 Secondary Flight Plan.*

Applicable to: ALL

RADIO NAV

Whenever a NAVAID IDENT is correctly decoded, in agreement with that published, no audio check is necessary.
Morse decoding is displayed on the ND for VOR/DME, VOR/TAC, DME, ADF, and on the PFD for ILS.
Preferably use the identifier for NAVAID entry.
If the ADF IDENT is not in the database, be sure to include a decimal point when tuning the frequency (e.g 315. or 325.7).



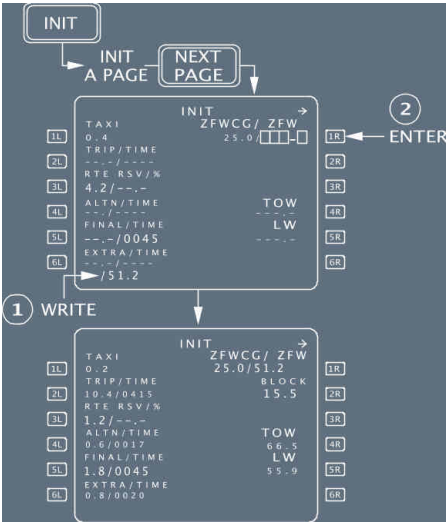
Note: *Whenever, the runway ILS is intented to be retained for guidance after the takeoff phase, it is recommended to manually tune the ILS by its identifier.*

FMGS DATA INSERTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

GROSS WEIGHT INSERTION

The flight system must have a number for aircraft gross weight (GW) in order to perform all the performance computations.



PROCEDURE

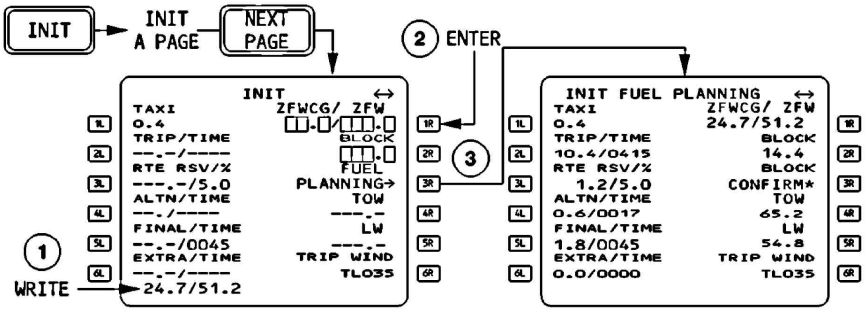
CHECK/MODIFY the ZFWCG
ENTER a ZFW
ENTER a BLOCK FUEL
CHECK/MODIFY the TAXI FUEL.
CHECK/MODIFY the RTE RSV.
CHECK/MODIFY the FINAL/TIME.

Note: - *As long as the final Load and Trim Sheet is not available, the flight crew may insert the estimated ZFWCG/ZFW in order to get fuel, time, and altitude estimates. The ZFWCG and ZFW must be updated with the final Load and Trim Sheet.*
- *Insert the ZFWCG/ZFW/BLOCK fuel preferably after F-PLN completion. If inserted before F-PLN completion, the FMGC automatically recomputes the predictions at each F-PLN change, including weight or wind changes. Therefore, F-PLN completion takes more time than normal.*

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

WEIGHT/CG INSERTION AND FUEL PLANNING

The flight crew must enter the Zero Fuel Weight (ZFW) and Zero Fuel Weight Center of Gravity (ZFWCG) values on the INIT B page, to allow the FMS to perform the fuel planning computations.



PROCEDURE

PRESS the INIT key, and the Next ("->") key to access the INIT B page.
ENTER the ZFWCG and ZFW value in the [1R] field.

The "FUEL PLANNING →" prompt appears in the [3R] field.

Note: *As long as the final Load and Trim Sheet is not available, the crew should insert the estimated ZFWCG/ZFW in order to get fuel estimates. The ZFWCG and ZFW values must be updated with the final Load and Trim Sheet values.*

CHECK/MODIFY the TAXI [1L] and RTE RSV [3L] values.

The TAXI and RTE RSV fields display the default values specified in the AMI file (for example, "0.4 t"for TAXI, and "5.0 %"for RTE RSV). The flight crew may modify these values.

CHECK/MODIFY the TRIP WIND value in the [6R] field.

If no wind profile has been entered in the F-PLN, the crew may enter an average TRIP WIND in this field, to have more realistic fuel/time predictions.

Note:
1. *If the crew has already defined a wind profile, even partially (such as climb wind), it is not possible to enter a TRIP WIND.*
2. *If the crew enters a TRIP WIND, and subsequently enters a wind profile on the WIND pages, the TRIP WIND will be erased, and the FMS will use the wind profile defined on the WIND pages for predictions computations.*

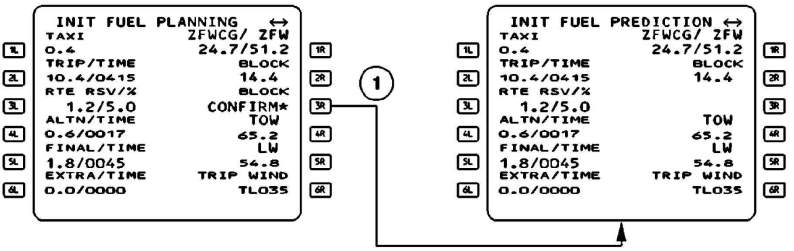
PRESS the FUEL PLANNING prompt [3R].

The FMS computes the required BLOCK fuel in order to have EXTRA fuel = 0, based on the parameters entered on the INIT and F-PLN pages. The computed BLOCK fuel value is displayed in the [2R] field, and a BLOCK CONFIRM prompt appears in the [3R] field.

Note: In order to obtain a realistic BLOCK fuel computation, the flight crew should ensure that the F-PLN initialization has been completed (including ALTN if necessary), and that flight parameters, such as CRZ FL, steps climbs (if any), and winds, have been inserted, before using the FUEL PLANNING function.

The flight crew must check the FMS-computed BLOCK fuel value against the actual block fuel required for the flight. Fuel planning must not be based only on FMS predictions.

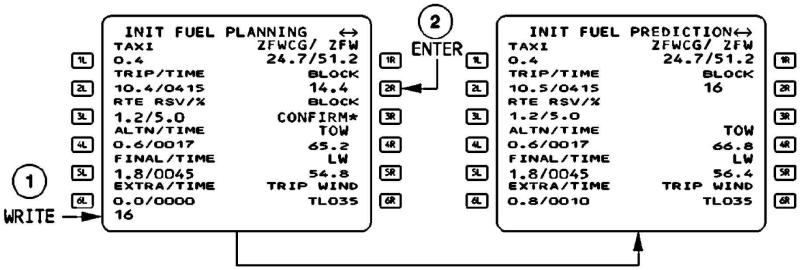
- **If the computed BLOCK fuel corresponds to the actual block fuel required for the flight:**



PRESS the BLOCK CONFIRM prompt [3R].

The FMS computes all the predictions, based on the computed BLOCK fuel.

- **If the computed BLOCK fuel does NOT correspond to the actual block fuel required for the flight:**



ENTER the desired BLOCK fuel in the [2R] field.

The FMS computes the predictions, based on the entered BLOCK fuel, and estimates the EXTRA fuel value.

- **When the BLOCK fuel has been entered:**

  CHECK/ MODIFY the FINAL/TIME [5L] values.

  If the crew modifies the FINAL or TIME values, the EXTRA fuel value will be modified accordingly.

  Note: *The ALTN value computed by the FMS may differ from the value retained on the operational flight plan, since some computation hypothesis (such as, for example, the route, wind profile, CRZ FL, CI) may differ.*

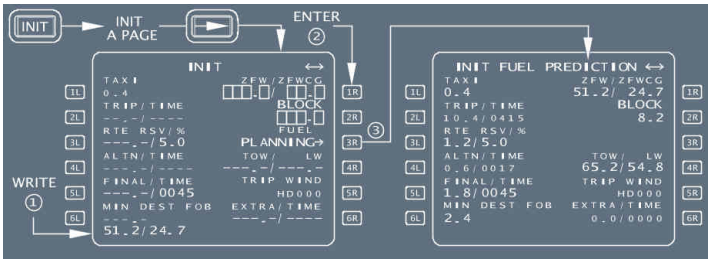
  PRINT the PREFLIGHT REPORT, if necessary

  When the final Load and Trim Sheet values (ZFWCG/ZFW/BLOCK) have been entered, and the FUEL PLANNING is completed, the flight crew may print the pre-flight report, which provides a copy of the F-PLN with the associated FMS predictions.

Applicable to: B-HSQ, B-HSR

WEIGHT/CG INSERTION AND FUEL PLANNING

The flight crew must enter the Zero Fuel Weight (ZFW) and Zero Fuel Weight Center of Gravity (ZFWCG) values on the INIT B page, to allow the FMS to perform the fuel planning computations.



PROCEDURE

PRESS the INIT key, and the Next ("→") key to access the INIT B page.
ENTER the ZFW and ZFWCG value in the [1R] field.

The "FUEL PLANNING →" prompt appears in the [3R] field.

Note: *As long as the final Load and Trim Sheet is not available, the crew should insert the estimated ZFW/ZFWCG in order to get fuel estimates. The ZFW and ZFWCG values must be updated with the final Load and Trim Sheet values.*

CHECK/MODIFY the TAXI [1L], RTE RSV [3L] and FINAL TIME [5L] values.

The TAXI, RTE RSV and FINAL TIME fields display the default values specified in the AMI file (for example, "0.4 t"for TAXI, "5.0 %"for RTE RSV and "0045" for FINAL TIME). The flight crew may modify these values.

Note: *At takeoff, the RTE RSV field will automatically be reset to 0. The RTE RSV fuel is then added to the EXTRA fuel, which ensures that the EXTRA fuel and MIN DEST FOB values are consistent in flight.*

ENTER an ALTN fuel value in the [4L] field, as necessary.

The flight crew may enter the ALTN fuel value planned on the Computerized Flight Plan (CFP), as necessary.

ENTER a MIN DEST FOB value in the [6L] field, as necessary.

Note: *MIN DEST FOB (equal to ALTN + FINAL) can be increased at flight crew discretion (e.g. when HOLD is expected at destination).*

ENTER the TRIP WIND value in the [5R] field, as necessary.

In no wind profile has been entered in the F-PLN, the crew may enter an average TRIP WIND in this field, to obtain more realistic fuel/time predictions before departure.

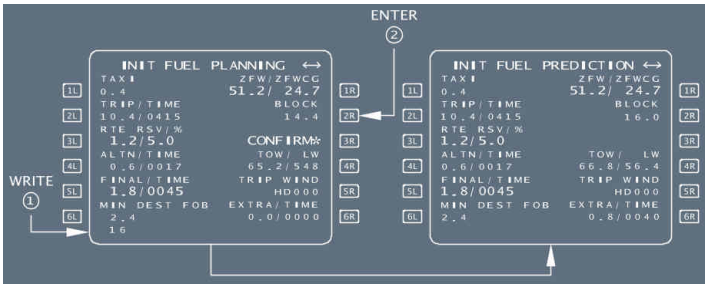
Note:
1. *The flight crew should only enter a TRIP WIND to obtain realistic fuel/time predictions, on ground. Then, the flight crew should enter a wind profile using the WIND pages, for fuel/time predictions in flight. As soon as flight crew has entered a wind profile on the WIND pages, the TRIP WIND will be erased.*
2. *If the crew has already defined a wind profile, even partially (such as climb wind), it is not possible to enter a TRIP WIND.*

ENTER the planned BLOCK fuel, as indicated in the computerized flight plan (CFP)

If the planned BLOCK fuel is not available, the crew may obtain a prediction of the minimum BLOCK fuel required for the flight by pressing the FUEL PLANNING prompt [3R].
Pressing this prompt makes the FMS compute the minimum required BLOCK fuel, which is the BLOCK fuel required to have EXTRA fuel = 0, based on the parameters entered on the INIT and F-PLN pages.
The computed BLOCK fuel value is displayed in the [2R] field, and a BLOCK CONFIRM prompt appears in the [3R] field.

Note: *In order to obtain a realistic fuel computation, the flight crew should ensure that the F-PLN initialization has been completed (including insertion of the ALTN F-PLN and/or ALTN fuel and/or MIN DEST FOB if necessary), and that flight parameters, such as CRZ FL, steps climbs (if any), and winds, have been inserted.*

- **When the final Load and Trim Sheet (LTS) data are available:**



ENTER the final ZFW/ZFWCG [1R], and the required BLOCK fuel [2R].

The FMS computes the predictions, based on the entered BLOCK fuel, and estimates the EXTRA fuel value.

CHECK the resulting computed data, against the data planned on the CFP: TRIP fuel, RTE RSV fuel, ALTN fuel, FINAL and EXTRA fuel values.

If necessary, the flight crew may modify the ALTN or FINAL fuel values.

PRINT the PREFLIGHT REPORT, if necessary.

When the final Load and Trim Sheet values (ZFW/ZFWCG/BLOCK) have been entered, the crew may print the pre-flight report, which provides a copy of the F-PLN with the associated FMS predictions.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

TAKEOFF WITH NO WEIGHT/CG ENTRY - WEIGHT/CG DATA LOST BY THE FMGC

If weight/CG data have not been entered, or if the FMGC loses the values due to a power interruption, managed speed will only be available for the takeoff phase (provided a V2 has been inserted).
After engine start, the MCDU displays “INITIALIZE WEIGHTS”.

If the crew does not enter weight/CG data, the following occurs:
- At takeoff, the Speed Reference System (SRS) mode is available,
- When the aircraft leaves the SRS mode, the target speed becomes the current speed and reverts to selected.

Note: *If the AP/FD has reverted to ALT or V/S (FPA) mode, the associated A/THR mode is SPEED. In this case, the system will probably reduce thrust, because the speed will be equal to, or greater than, the target speed.*

- **To regain a normal speed target, the flight crew must:**
  SELECT the appropriate speed on the FCU and PULL the speed knob
  INSERT the GW/CG values on the FUEL PRED page.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

TAKEOFF WITH NO GROSS WEIGHT ENTRY (GW)-GROSS WEIGHT LOST BY THE FMGS

If a GW is not entered, or if the FMGS loses the values due to a power interruption, managed speed will only be available for the takeoff phase (provided a V2 has been inserted).
After engine start, the MCDU displays “INITIALIZE WEIGHTS”.

If the crew does not respond, the following occurs:
- At takeoff, the Speed Reference System (SRS) mode remains active until the aircraft reaches acceleration altitude (ACC ALT), or engages another vertical mode.
- When the aircraft leaves the SRS mode, the target speed becomes the current speed and is no longer managed.

Note: If the AP/FD has reverted to ALT or V/S (FPA) mode, the associated A/THR mode is SPEED. In this case, the system will probably reduce thrust, because the speed will be equal to, or greater than, the target speed.

- **To regain a normal speed target, the flight crew must:**
  SELECT the appropriate speed on the FCU and PULL out the speed knob
  INSERT the FOB, if necessary, and GW on the FUEL PRED page.
  PRESS the SPD pb on FCU to get managed speed target.

Applicable to: B-HSQ, B-HSR

TAKEOFF WITH NO WEIGHT/CG DATA

If the crew does not enter ZFW/ZFWCG data prior takeoff, or if the FMGC looses these values due to a power interruption, the following will occur:
- At takeoff, the Speed Reference System (SRS) mode is available (provided a V2 has been inserted)
- When the aircraft leaves the SRS mode, the target speed becomes the current speed and reverts to selected.

Note: If the AP/FD has reverted to ALT or V/S (FPA) mode, the associated A/THR mode is SPEED. In this case, the system will probably reduce thrust, because the speed will be equal to, or greater than, the target speed.

- **When appropriate, to regain FMS predictions and associated managed modes:**
  INSERT the ZFW/ZFWCG values on the FUEL PRED page.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

INSERTING WEIGHT/CG AFTER ENGINE START

The flight crew must enter the ZFWCG/ZFW values on INIT B page prior to engine start. After engine start, the flight crew can enter the GW/CG values on the FUEL PRED page.

PRESS to the FUEL PRED key.
INSERT the GW/CG values in the [4R] field.

This allows predictions and performance computation.

Note: Before flight crew entry, the CG is defaulted to 25 %.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

INSERTING GW AND CG AFTER ENGINE START

The pilot must enter the ZFW and ZFWCG on the INIT B page before engine start. If this is not done, the pilot can enter the GW and CG after engine start on the FUEL PRED page.

ACCESS to the FUEL PRED PAGE.
INSERT the gross weight and center of gravity. This allows performance computation.

Applicable to: B-HSQ, B-HSR

INSERTING WEIGHT/CG DATA AFTER ENGINE START

The flight crew must enter the ZFW/ZFWCG values on INIT B page prior to engine start. If these data have not been entered at engine start, the MCDU displays the “INITIALIZE WEIGHTS” amber message in the scratchpad. After engine start, the crew should enter the ZFW/ZFWCG values on the FUEL PRED page.

PRESS to the FUEL PRED key.
INSERT the ZFW/ZFWCG values in the [4R] field.

This allows predictions and performance computation.

CHECK the resulting computed data, against the data planned on the CFP: TRIP fuel, RTE RSV fuel, ALTN fuel, FINAL and EXTRA fuel values.

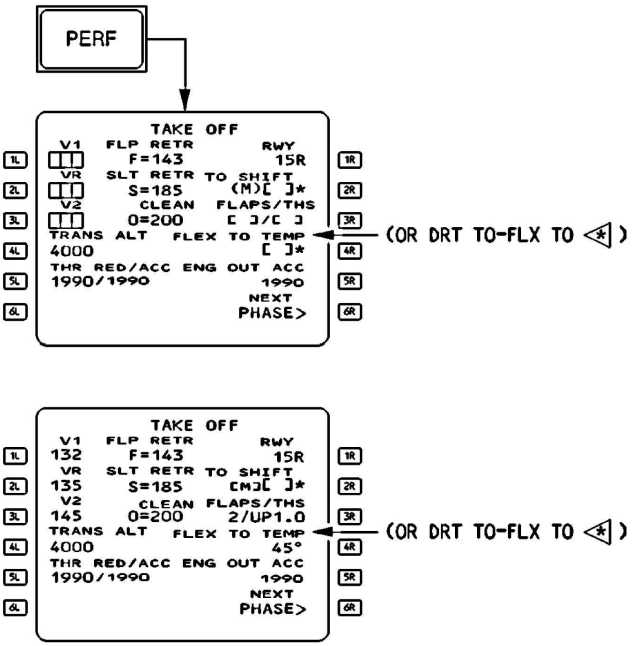
If necessary, the flight crew may modify the ALTN or FINAL fuel values.

PRINT the PREFLIGHT REPORT, if necessary.

When the final load sheet values (ZFW/ZFWCG/BLOCK) have been entered, the crew may print the pre-flight report, which provides a copy of the F-PLN with the associated FMS predictions.

Applicable to: ALL

TAKEOFF DATA INSERTION



PROCEDURE

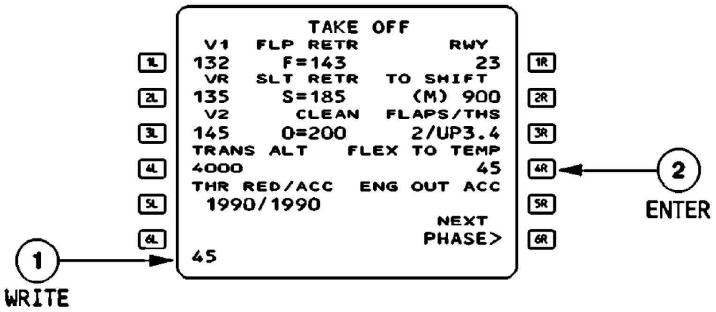
PRESS the PERF key on the MCDU.
WRITE successively and ENTER : V1, VR, V2.
WRITE successively and ENTER T.O. SHIFT and FLX TEMP or DRT TO
CHECK/MODIFY the THR RED ALT (Thrust reduction altitude) See *.
CHECK/MODIFY the ACC ALT (acceleration altitude) See *.
CHECK/MODIFY the ENG OUT ACC (engine out acceleration altitude) See *.
CHECK/MODIFY the TRANS ALT (transition altitude) See *
CHECK V1, V2 on PFD See **

* *Altitudes less than 400 ft above airfield elevation cannot be selected.*

** *If the PFD does not display V2 at the top of its speed scale, check that at least one FD is ON.*

ENTERING A FLEX TEMPERATURE

WRITE the desired flex temperature in the scratchpad and ENTER using the [4R] key.



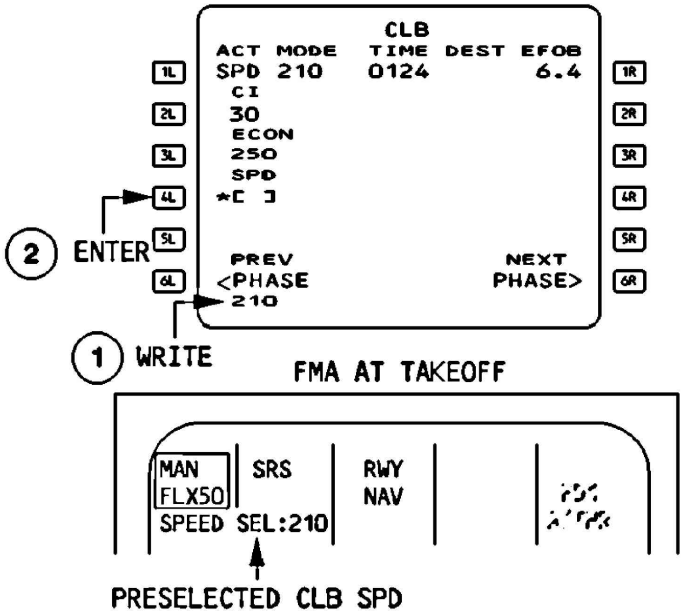
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

CLIMB SPEED PRESELECTION

If the managed speeds for the initial climb are not suitable, the pilot can preselect an appropriate climb speed on the “PERF CLB”page, as long as the climb phase is not active.

The CLB SPD preselection applies, when the:

- ATC specifies an initial climb speed.
- Initial climb speed must be lower than normal because:
  - There are to be turns greater than 120 ° in the initial climb out.
  - Obstacle clearance, or some other situation, requires a high climb angle.
  - The airfield has a risk area to be quickly cleared (birds reported, for example).



PROCEDURE

PRESS the PERF key on the MCDU.

The PERF TAKE OFF page is displayed.

SELECT the "NEXT PHASE" [6R] key to display the CLB page.
WRITE a climb speed and ENTER it.
To revert to managed speed, select ECON by pressing [3L].

When the aircraft is transitioning into the climb phase, the preselected value becomes the target speed:

- The selected speed target is active.
- The primary flight display shows the target speed in blue.
- The FCU's speed window displays the new speed or Mach number.

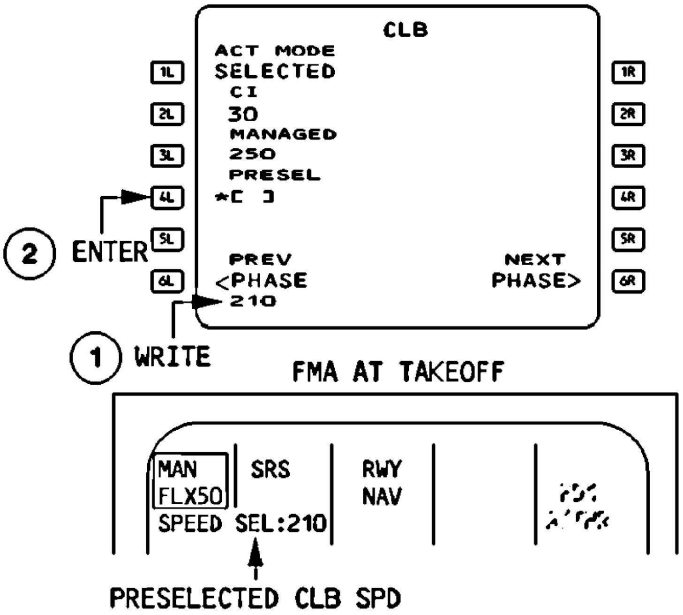
Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

CLIMB SPEED PRESELECTION

If the managed speeds for the initial climb are not suitable, the pilot can preselect an appropriate climb speed on the "PERF CLB"page, as long as the climb phase is not active.

The CLB SPD preselection applies, when the:

- ATC specifies an initial climb speed.
- Initial climb speed must be lower than normal because:
  - There are to be turns greater than 120 ° in the initial climb out.
  - Obstacle clearance, or some other situation, requires a high climb angle.
  - The airfield has a risk area to be quickly cleared (birds reported, for example).



PROCEDURE

PRESS the PERF key on the MCDU.

The PERF TAKE OFF page is displayed.

SELECT the “NEXT PHASE” [6R] key to display the CLB page.

WRITE a climb speed and ENTER it.

To revert to managed speed, select MANAGED by pressing [3L].

When the aircraft is transitioning into the climb phase, the preselected value becomes the target speed:

- The selected speed target is active.
- The primary flight display shows the target speed in blue.
- The FCU's speed window displays the new speed or Mach number.

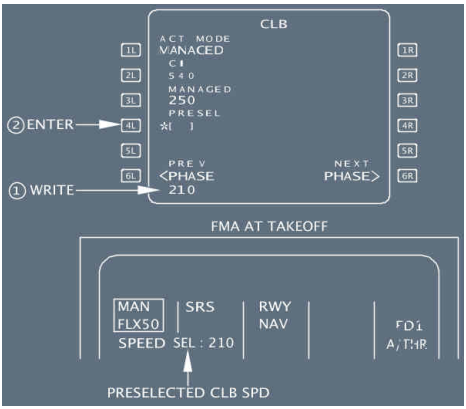
Applicable to: B-HSQ, B-HSR

CLIMB SPEED PRESELECTION

If the managed speeds for the initial climb are not suitable, the pilot can preselect an appropriate climb speed on the "PERF CLB"page, as long as the climb phase is not active.

The CLB SPD preselection applies, when the:

- ATC specifies an initial climb speed.
- Initial climb speed must be lower than normal because:
  - There are to be turns greater than 120 ° in the initial climb out.
  - Obstacle clearance, or some other situation, requires a high climb angle.
  - The airfield has a risk area to be quickly cleared (birds reported, for example).



PROCEDURE

PRESS the PERF key on the MCDU.

The PERF TAKE OFF page is displayed.

SELECT the PERF CLB page by pressing [6 R] ("NEXT PHASE" prompt).
WRITE a climb speed and ENTER it.
To revert to managed speed, select MANAGED by pressing [3L].

When the aircraft is transitioning into the climb phase, the preselected value becomes the target speed:

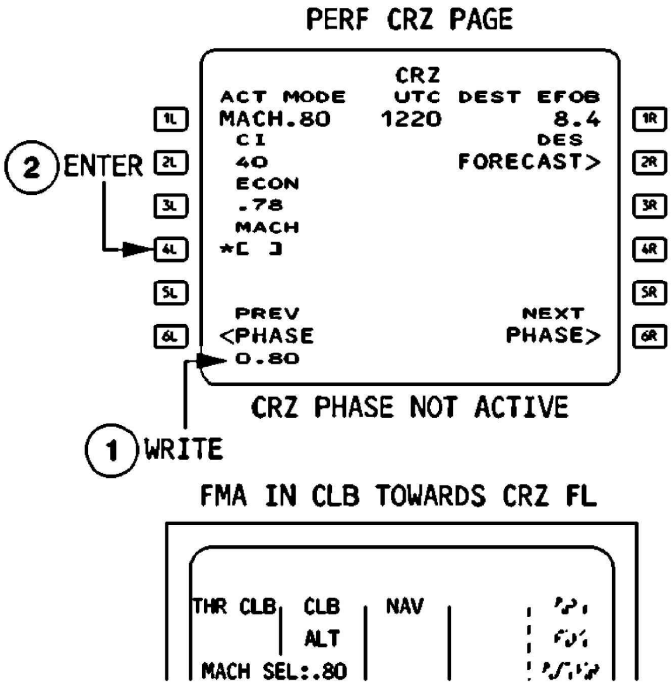
- The selected speed target is active.
- The primary flight display shows the target speed in blue.
- The FCU's speed window displays the new speed or Mach number.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

CRUISE MACH (SPEED) PRESELECTION

The pilot preselects a cruise Mach, when a Mach number other than the ECON cruise Mach number is required.

When the aircraft transitions to the cruise phase, the speed target symbol goes to the preselected value and MACH (or SPD) becomes selected (blue target on PFD, target MACH shown in the speed/Mach window of the FCU).



PROCEDURE

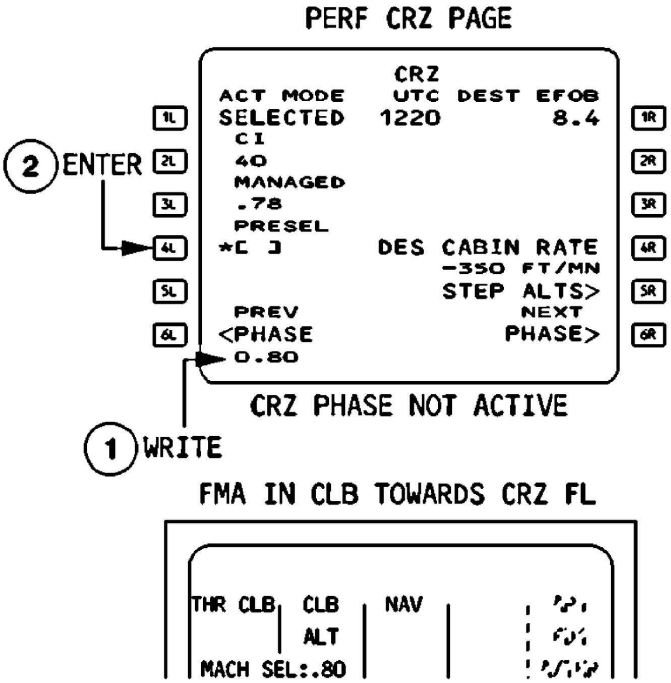
PRESS the PERF key on the MCDU.
PRESS the "NEXT PHASE" [6R] key on the MCDU, until the CRZ page is accessed.
WRITE a cruise Mach (or speed) in the scratchpad and ENTER it in [4L].
To revert to managed speed, PRESS [3L].

When the cruise phase is active, you cannot preselect a cruise Mach or speed.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

CRUISE MACH (SPEED) PRESELECTION

The pilot preselects a cruise Mach, when a Mach number other than the ECON cruise Mach number is required.
When the aircraft transitions to the cruise phase, the speed target symbol goes to the preselected value and "SELECTED" becomes the active speed mode (blue target on PFD, target MACH shown in the speed/Mach window of the FCU).



PROCEDURE

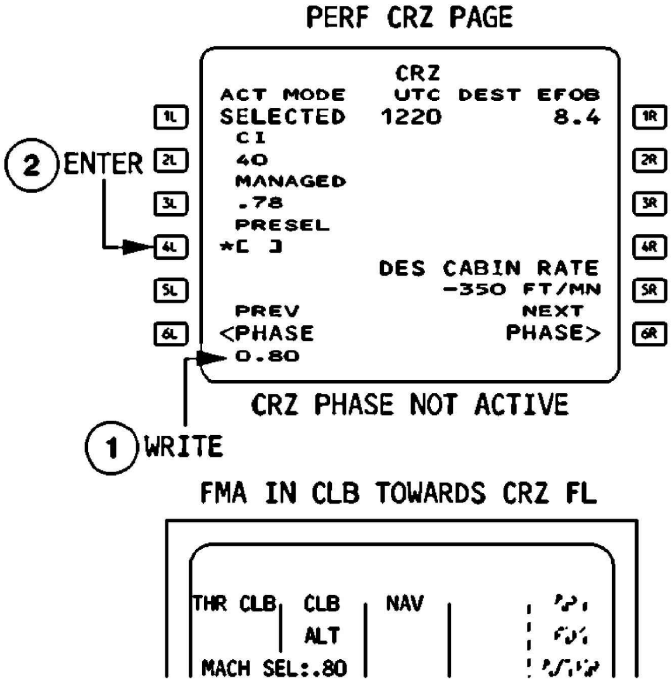
PRESS the PERF key on the MCDU.
PRESS the "NEXT PHASE" [6R] key on the MCDU, until the CRZ page is accessed.
WRITE a cruise Mach (or speed) in the scratchpad and ENTER it in [4L].
To revert to managed speed, PRESS [3L].

When the cruise phase is active, you cannot preselect a cruise Mach or speed.

Applicable to: B-HSQ, B-HSR

CRUISE MACH (SPEED) PRESELECTION

The pilot preselects a cruise Mach, when a Mach number other than the ECON cruise Mach number is required.
When the aircraft transitions to the cruise phase, the speed target symbol goes to the preselected value and "SELECTED" becomes the active speed mode (blue target on PFD, target MACH shown in the speed/Mach window of the FCU).



PROCEDURE

PRESS the PERF key on the MCDU.
PRESS the "NEXT PHASE" [6R] key on the MCDU, until the CRZ page is accessed.
WRITE a cruise Mach (or speed) in the scratchpad and ENTER it in [4L].
To revert to managed speed, PRESS [3L].

When the cruise phase is active, you cannot preselect a cruise Mach or speed.

Applicable to: ALL

ENTERING A HEADING/TRACK PRESET FUNCTION

The heading/track preset allows the pilot to preset a takeoff or go-around heading or track before commanding the aircraft to take up that heading or track (manual activation).
The flight crew can enter a heading or a track preset while the aircraft is on the ground and until takeoff.

PROCEDURE

- **Before takeoff :**

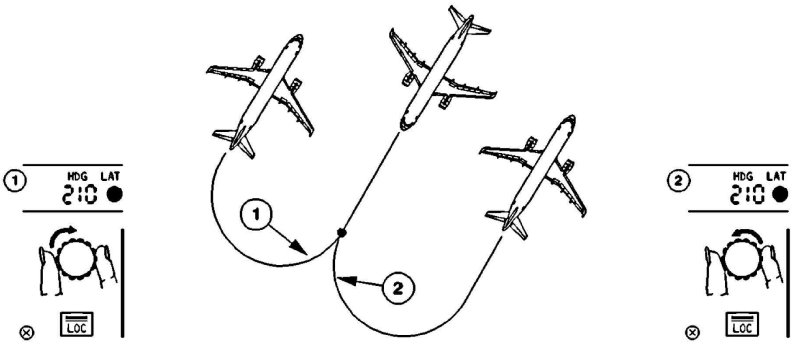
  SET the appropriate HDG or TRK in the FCU window.

  This disarms the navigation mode and allows the runway mode to remain engaged after takeoff.

- **After takeoff :**

  PULL HDG/TRK knob.

  The heading or track mode engages on the preset value.



The direction in which the pilot rotates the HDG/TRK selection knob usually determines the direction of the turn. A left rotation (decreasing heading) produces a left turn ; a right rotation produces a right turn.

However, when a heading has been preset before takeoff or go-around, the direction of the turn will be such as to cause the shortest turn at the moment of engagement.

CANCELLING THE HEADING/TRACK PRESET FUNCTION

The pilot can cancel the heading preset by pushing the HDG/TRK knob back in again. This engages or arms the NAV mode.

FMGS RE-INITIALIZATION AFTER A CANCELED FLIGHT

Applicable to: ALL

If the flight crew initially prepared a flight with all the data associated with this flight (takeoff speeds, winds, etc.), and if this flight is later canceled and replaced by another flight, the flight crew may use the following procedure to initialize the FMGS again:

PREPARE the new flight data in the secondary flight plan, using SEC INIT A, SEC INIT B, and SEC PERF pages
ACTIVATE the secondary flight plan.

Note: *When the flight crew activates the secondary flight plan, the following data of the primary flight plan is lost if the secondary flight plan does not include any replacement data:*

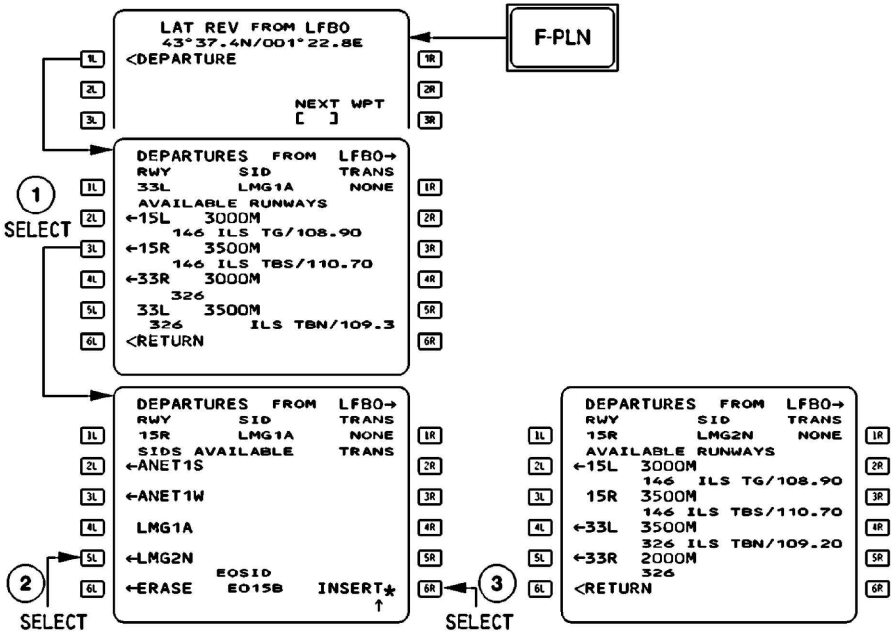
- *Alternate data*
- *Winds and cruise TEMP at waypoints as inserted on CRZ WIND pages*
- *Departure and arrival selection (STAR, APP, RWY) and approach parameters (QNH, TEMP, WIND, TRANS ALT, VAPP, MDA/MDH, DH, LDG CONF)*
- *Altitude, speed, and time constraints*
- *Steps*
- *CMS*
- *Offsets*
- *Flaps/THS*
- *Preselected cruise and descent speeds.*

Intentionally left blank

Before Pushback or Start

CHANGE OF RUNWAY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF



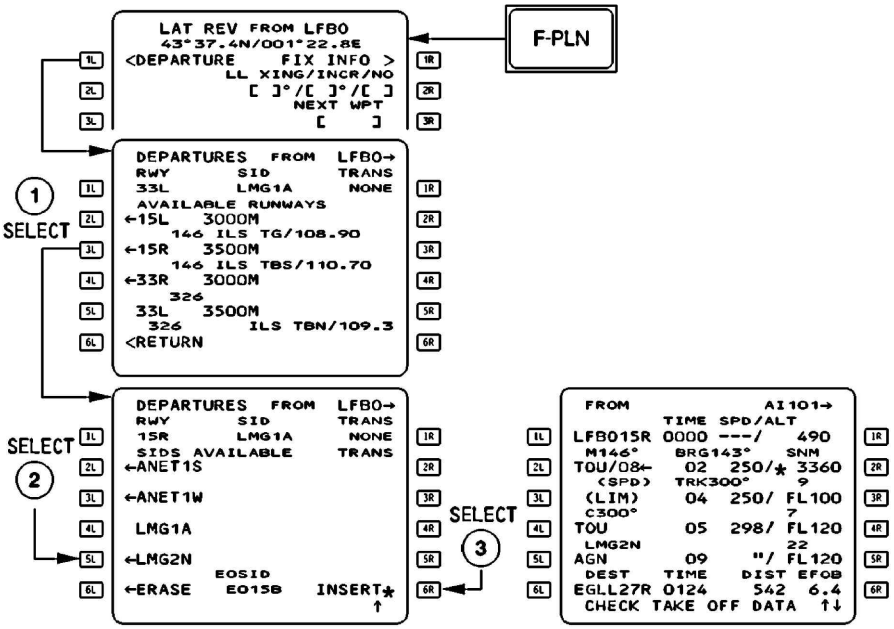
PRESS the F-PLN key on MCDU.
SELECT the LAT REV page at origin.
SELECT the DEPARTURE prompt [1L].
SELECT the new RWY in use.
SELECT the appropriate SID and TRANS.
CHECK the resulting temporary F-PLN and INSERT it.

ENTER the new V1, VR, V2, FLX TO TEMP (or derated thrust if installed) and CONFIGURATION as appropriate.

Note: *If the previously selected SID is compatible with the new runway, it automatically appears in the temporary flight plan. Any revision the pilot may have made to the previous SID will not be transferred.*
If the pilot still wants it, he has to reenter it.

CHANGE OF RUNWAY

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI



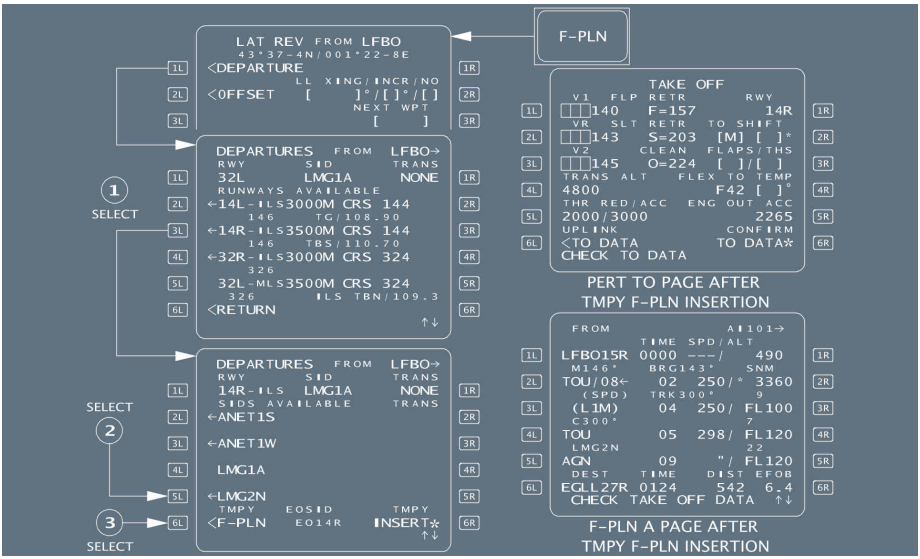
PRESS the F-PLN key on the MCDU.
SELECT the LAT REV at origin.
SELECT the DEPARTURE prompt [1L].
SELECT the new RWY in use.
SELECT the appropriate SID and TRANS.
CHECK the resulting temporary F-PLN and INSERT it.
CHECK TAKE OFF DATA comes up in the scratchpad if the PERF TO page had been filled in.

ENTER the new V1, VR, V2, FLEX TEMP or CONF, as appropriate.

Note: *If the previously selected SID is compatible with the new runway, it automatically appears in the temporary flight plan. Any revision the pilot may have made to the previous SID will not be transferred.*
If the pilot still wants it, he has to reenter it.

CHANGE OF RUNWAY

Applicable to: B-HSQ, B-HSR



PRESS the F-PLN key on the MCDU.
SELECT the LAT REV at origin.
SELECT the DEPARTURE prompt [1L].
SELECT the new RWY in use.
The "CHECK TAKE-OFF DATA" message is displayed.
CHECK/SELECT the appropriate SID and TRANS.
CHECK and INSERT the TMPY F-PLN, or continue with next revision.
PRESS the PERF key to access PERF TAKEOFF page.
CHECK the V1, VR, V2 and FLEX values displayed after the amber boxes. If these values are correct, PRESS [6R] to confirm and insert them. Else, ENTER new values.

ENTER the new V1, VR, V2, FLEX TEMP or CONF, as appropriate.

The previously-entered values, adjacent to the boxes, may be re-selected by pressing the CONFIRM TO DATA on [6R].*

Note: In case of a runway change, any previous lateral modification performed on the active DEPARTURE procedure may lead to additional waypoint stacking in the temporary F-PLN. The crew has to check and revise it, as necessary.
Refer to DSC-22_20-30-10-18 Changing the Departure/Arrival.

TAKEOFF FROM INTERSECTION

Applicable to: ALL

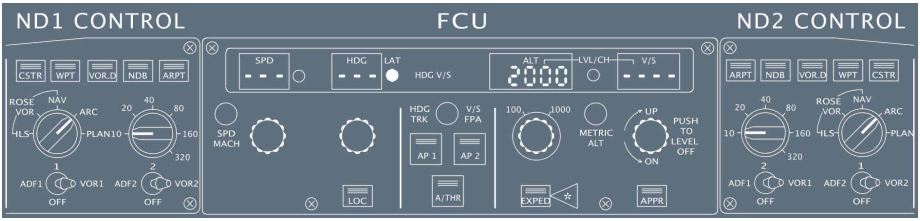
Use RTOW or FCOM to revise takeoff parameters :
PRESS the [PERF] key on MCDU
ENTER the takeoff shift
ENTER the new V1, VR, V2, FLX TEMP, or CONF, as appropriate

Note: The insertion of the shift in takeoff position permits the system to make an accurate revision to its navigation data at takeoff.

Taxi

FCU SELECTION FOR TAKEOFF

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

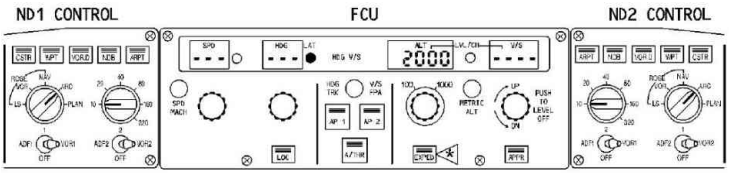


PROCEDURE

ENSURE that HDG –V/S modes are selected (change over pb).
CONFIRM or SELECT the first cleared altitude
CROSS CHECK on PFD the target altitude
CONFIRM both FDs ON

FCU SELECTION FOR TAKEOFF

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI



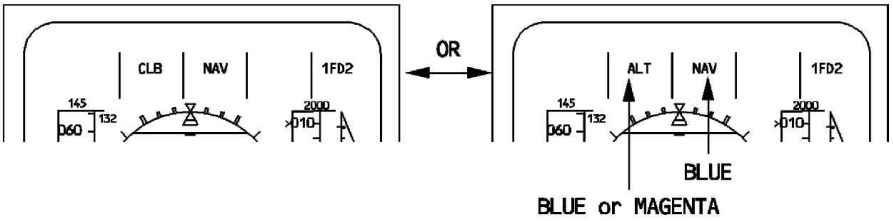
PROCEDURE

ENSURE that HDG –V/S modes are selected (change over pb).
CONFIRM or SELECT the first cleared altitude
CROSS CHECK on PFD the target altitude
CONFIRM both FDs ON

FMA MODE CHECK

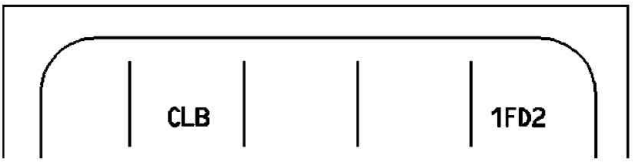
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

CHECK that the FMA CLB (or ALT) mode is armed



Note: *ALT (in blue or magenta) may be displayed instead of CLB if the FCU altitude or a constraint is set at or below the acceleration altitude.*

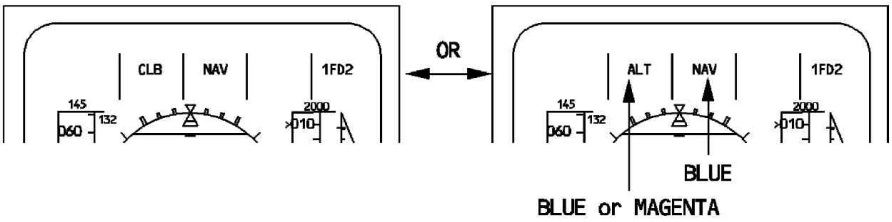
If a HDG/TRK was preset, NAV is disarmed.



FMA MODE CHECK

Applicable to: B-HSQ, B-HSR

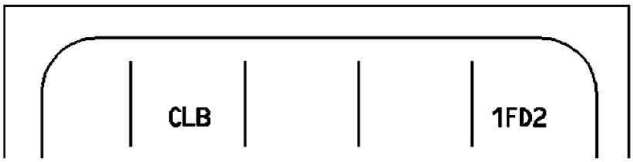
CHECK that the FMA CLB (or ALT) mode is armed



Note: *ALT (in blue or magenta) may be displayed instead of CLB if the FCU altitude or a constraint is set at or below the acceleration altitude.*

Note: *If a radar-vector standard instrument departure (SID) has been selected, a F-PLN discontinuity immediately follows the departure runway, and NAV mode is not armed. After takeoff, RWY TRK mode engages until the crew selects a HDG or performs a DIR TO.*

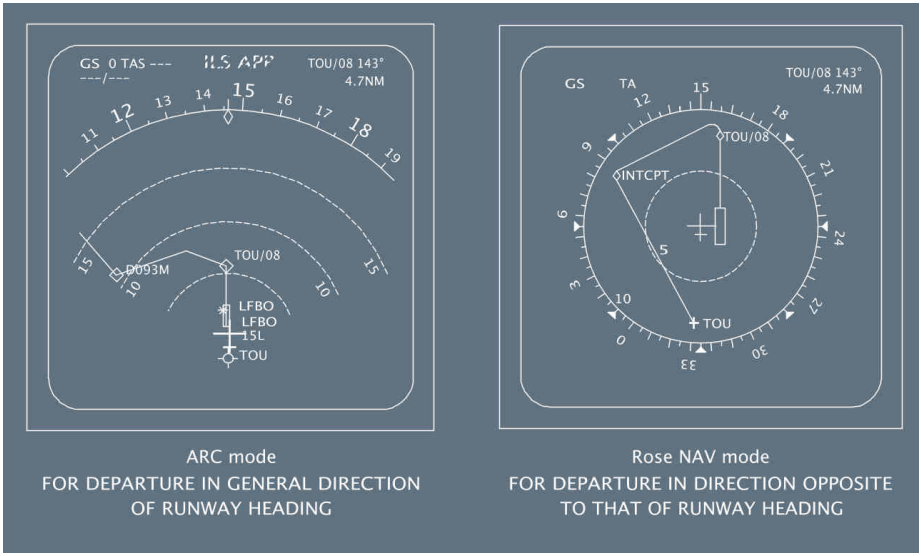
If a HDG/TRK was preset, NAV is disarmed.



SELECTING A NAVIGATION DISPLAY

Applicable to: ALL

SET the minimum range to display the first waypoint after departure or as required for weather radar.

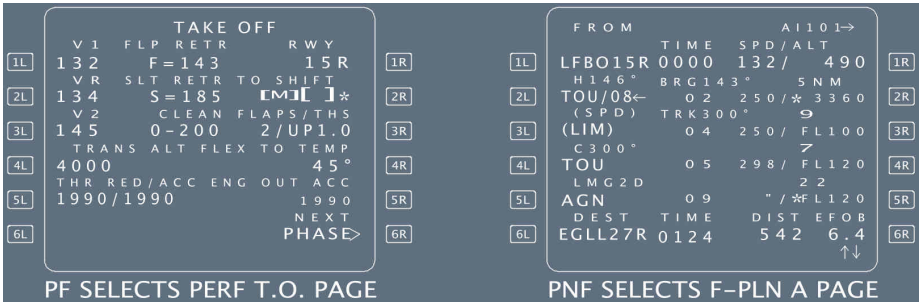


ARC mode
FOR DEPARTURE IN GENERAL DIRECTION OF RUNWAY HEADING

Rose NAV mode
FOR DEPARTURE IN DIRECTION OPPOSITE TO THAT OF RUNWAY HEADING

SELECTING TAKEOFF DISPLAYS FOR PILOT'S AND COPILOT'S MCDU

Applicable to: ALL



PF SELECTS PERF T.O. PAGE

PNF SELECTS F-PLN A PAGE

Takeoff

MONITORING THE TAKEOFF

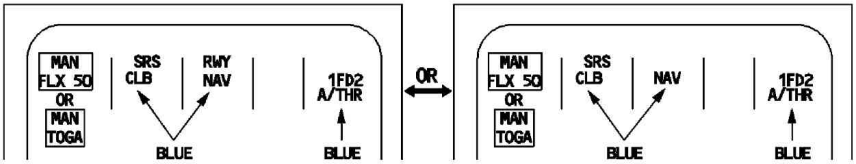
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

- **At power set (thrust levers in FLX or TOGA position)**

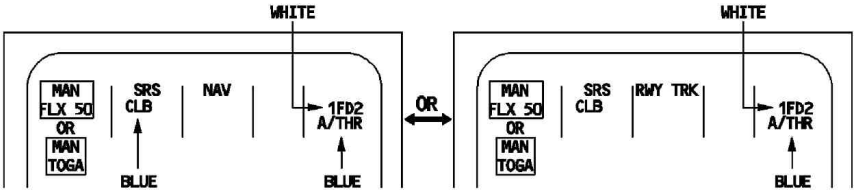
  CHECK that the navigation is updated to the runway threshold by verifying that the aircraft symbol is centered on the runway threshold of the navigation display.

  CHECK the FMA for appropriate mode selection

  Note: - *RWY mode appears if an ILS is tuned to a station corresponding to the departure runway. Otherwise no lateral mode comes up until the aircraft has lifted off.*



- **At 30 ft**
  - **If NAV is armed,** it engages automatically.
  - **If NAV is not armed,** RWY TRK mode engages and remains displayed until the crew selects another lateral mode.



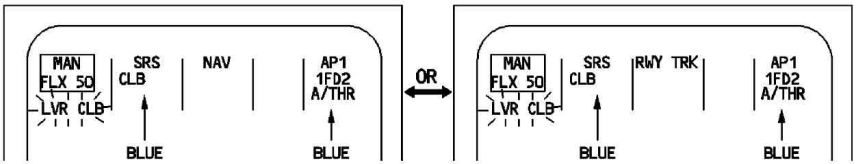
- **At 100 ft**

  Engage AP1 or AP2.

  The FMGS has an internal delay that prevents the AP to be engaged during 5 s after lift-off.

- **At thrust reduction altitude**

  "LVR CLB"flashes in the first column of the FMA



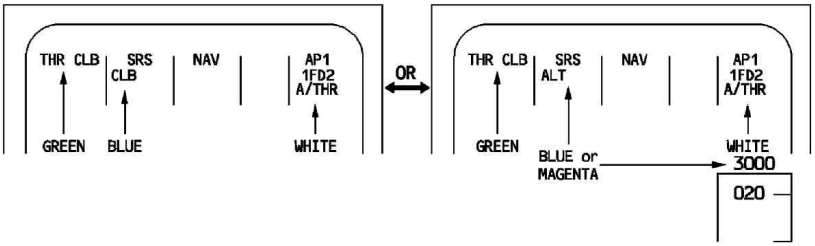
Procedure

SET the thrust levers to the CL detent

A/THR activates automatically

CHECK that A/THR turns to white in the 5th FMA column.

CHECK that THR CLB appears in green in the first column.



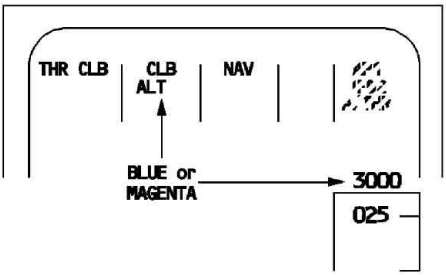
Depending on the next level off altitude, CLB or ALT is armed and displayed in the second column.

ALT is armed:

- *in blue if the next predicted level-off is the FCU-selected altitude (target altitude blue at the top of the ALT scale)*
- *in magenta if the next predicted level-off is an ALT CSTR (target altitude magenta at the top of the ALT scale)*

● **At acceleration altitude**

The vertical phase automatically switches to climb.
CLB mode engages. The target speed jumps to initial climb speed on the PFD.



Procedure

CHECK that "CLB"appears in green in the second FMA column.

- *The speed reference system (SRS) mode remains engaged until CLB phase is engaged, which occurs at ACCEL ALT or at any other vertical mode engagement, whichever comes first.*
- *If during takeoff the FCU altitude is set below the current aircraft altitude, the system ignores the FCU altitude and the aircraft remains in SRS mode until the pilot selects an altitude above the aircraft altitude or engages any other mode.*

MONITORING THE TAKEOFF

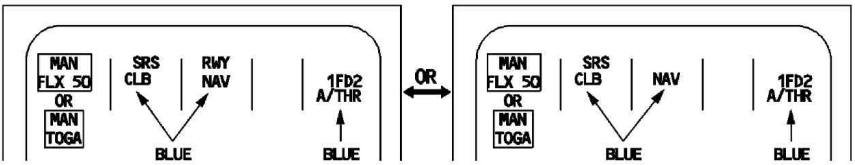
Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

● **At power set (thrust levers in FLX or TOGA position)**

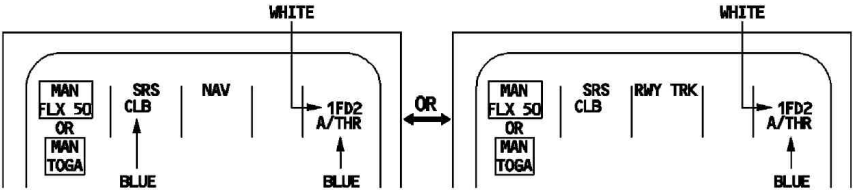
CHECK that the navigation is updated to the runway threshold by verifying that the aircraft symbol is centered on the runway threshold of the navigation display.

CHECK the FMA for appropriate mode selection

Note: - *RWY mode appears if an ILS is tuned to a station corresponding to the departure runway. Otherwise no lateral mode comes up until the aircraft has lifted off.*



- **At 30 ft**
  - **If NAV is armed,** it engages automatically.
  - **If NAV is not armed,** RWY TRK mode engages and remains displayed until the crew selects another lateral mode.



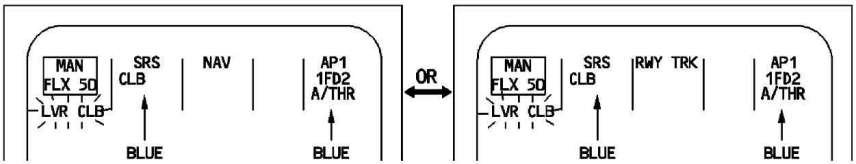
- **At 100 ft**

  Engage AP1 or AP2.

  The FMGS has an internal delay that prevents the AP from engaging 5 s after liftoff and if the aircraft is below 100 ft.

- **At thrust reduction altitude**

  "LVR CLB"flashes in the first column of the FMA



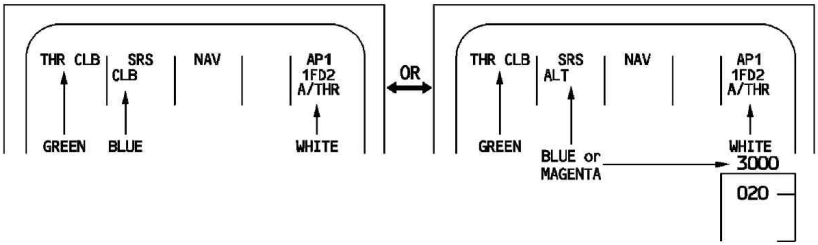
Procedure

SET the thrust levers to the CL detent

A/THR activates automatically

CHECK that A/THR turns to white in the 5th FMA column.

CHECK that THR CLB appears in green in the first column.



Depending on the next level off altitude, CLB or ALT is armed and displayed in the second column.

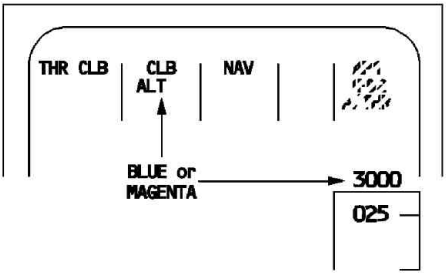
ALT is armed:

- *in blue if the next predicted level-off is the FCU-selected altitude (target altitude blue at the top of the ALT scale)*
- *in magenta if the next predicted level-off is an ALT CSTR (target altitude magenta at the top of the ALT scale)*

● **At acceleration altitude**

The vertical phase automatically switches to climb.

CLB mode engages. The target speed jumps to initial climb speed on the PFD.



Procedure

CHECK that "CLB"appears in green in the second FMA column.

- *The speed reference system (SRS) mode remains engaged until CLB phase is engaged, which occurs at ACCEL ALT or at any other vertical mode engagement, whichever comes first.*
- *If during takeoff the FCU altitude is set below the current aircraft altitude, the system ignores the FCU altitude and the aircraft remains in SRS mode until the pilot selects an altitude above the aircraft altitude or engages any other mode.*

PRESELECTING A HDG OR A TRK

Applicable to: ALL

PROCEDURE

● **If a HDG or a TRK was preselected on the ground :**

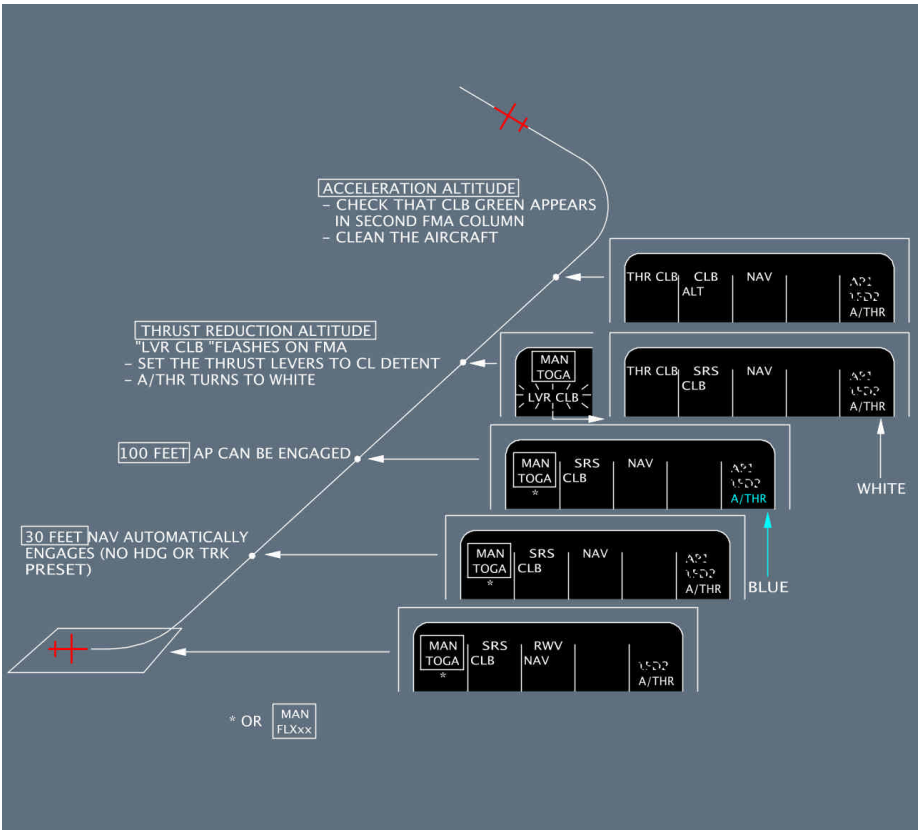
PULL OUT the HDG/TRK selector knob when required

CHECK that the HDG/TRK mode is active and displayed on the FMA

When a HDG or TRK is preset, OP CLB mode will engage at the acceleration altitude. (CLB mode is not available in HDG/TRK mode).

NORMAL TAKEOFF PROFILE

Applicable to: ALL



NO FLIGHT DIRECTOR TAKEOFF

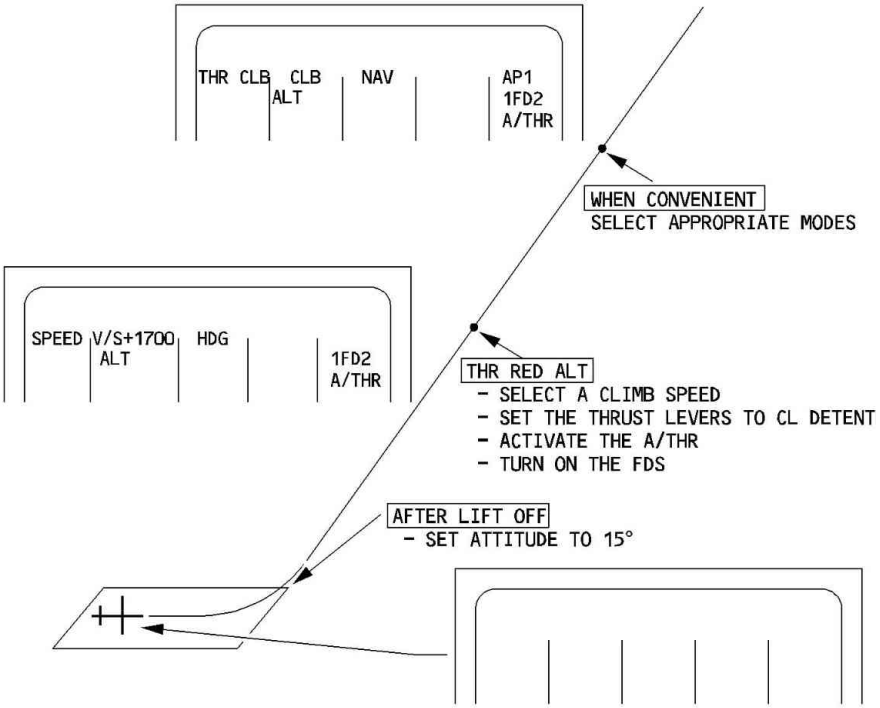
Applicable to: ALL

If a takeoff is initiated without FDs, the system responds as follow:

- There are no FD bars.
- There is no A/THR arming.
- There is no guidance available.

- The target speed on the PFD is that selected on the FCU or is defaulted to 100 kt.
- Setting the thrust levers to the CL detent does not activate A/THR.

Note: Do not engage the autothrust prior to selecting a target speed on the FCU.



PROCEDURE

Establish initial climb of 15 °

- **When reaching the thrust reduction altitude (THR RED ALT):**

  SELECT a climb speed.

  SET the thrust levers to CL detent.

  ACTIVATE the autothrust.

  TURN ON the FDs (basic modes engage).

  SELECT appropriate mode.

Failure of both FDs after the start of takeoff:

- *The FD bars disappear.*
- *The FCU window displays the target speed, which synchronizes on V2, or the current speed (if it is higher).*
- *The autothrust remains armed.*
- *At thrust reduction altitude, LVR CLB flashes. If the pilot set the thrust levers to the CLB detent, the autothrust becomes active in selected SPD mode (no FDs selected).*
  If the current speed is greater than the target speed, the thrust decreases.
- *At acceleration altitude the target speed does not change, since it is selected.*

TAKEOFF WITH NO V2 ENTRY

Applicable to: ALL

If V2 is not inserted, the speed reference system (SRS) will not engage for takeoff.
5 s after lift off, V/S mode will engage. When V/S engages the current airspeed becomes the FCU target speed.

To regain a normal speed target, the pilot must :

SELECT the appropriate climb speed on the FCU and PULL out the knob.

- **At ACC ALT :**

  PUSH the A/THR pb on the FCU.

  SET the thrust levers to CL detent.

  PUSH in the SPD selector knob to get a managed speed target.

TAKEOFF USING THE LOCALIZER OF THE OPPOSITE RUNWAY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

- **If the localizer, of the ILS associated with the opposite runway, must be used for takeoff:**

  SELECT the RAD NAV PAGE.

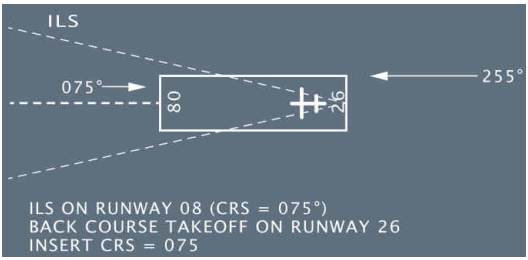
  ENTER the ILS IDENT.

  If the ILS is in the database, the system tunes the proper frequency.
  Check that the ILS front course is displayed in the CRS field.

  Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

  SET the appropriate frequency, and SET the ILS front course in the CRS field.



DESELECT the ILS pb on the FCU.

Since the PFD displays reverse deviation.

SELECT ROSE-ILS on one ND.

TAKEOFF USING THE LOCALIZER OF THE OPPOSITE RUNWAY

Applicable to: B-HSJ, B-HSK, B-HTG, B-HTH, B-HTI

- **If the localizer, of the ILS associated with the opposite runway, must be used for takeoff:**

  SELECT the RAD NAV PAGE.

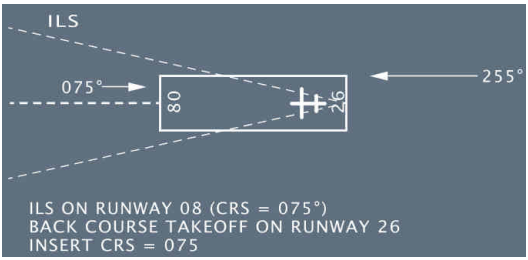
  ENTER the ILS IDENT.

  If the ILS is in the database, the system tunes the proper frequency.
  Check that the ILS front course is displayed in the CRS field.

  Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

  SET the appropriate frequency, and SET the ILS front course in the CRS field.



DESELECT the LS pb on the FCU.

Since the PFD displays reverse deviation.

SELECT ROSE ILS on one ND.

TAKEOFF USING THE LOCALIZER OF THE OPPOSITE RUNWAY

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- **If the localizer, of the ILS associated with the opposite runway, must be used for takeoff:**

  SELECT the RAD NAV PAGE.

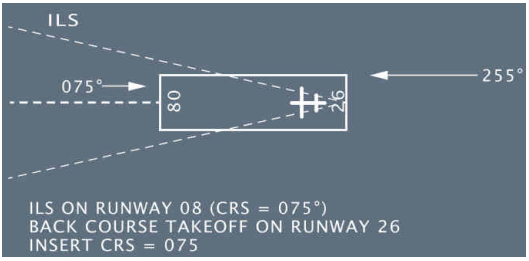
  ENTER the ILS IDENT.

  If the ILS is in the database, the system tunes the proper frequency.
  Check that the ILS front course is displayed in the CRS field.

  Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

  SET the appropriate frequency, and SET the ILS front course in the CRS field.



DESELECT the LS pb on the FCU.

Since the PFD displays reverse deviation.

DESELECT the LS pb on ISIS.

Since ISIS displays LOC reverse deviation.

SELECT ROSE-ILS on one ND.

Intentionally left blank

Climb

MONITORING THE CLIMB PHASE

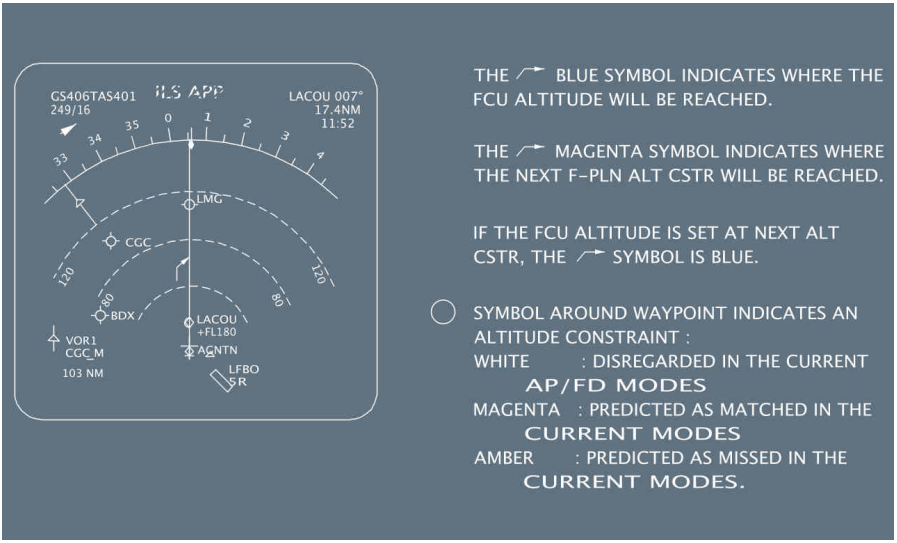
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

The PF MCDU should display the PERF CLB page allowing him to monitor the climb.
The PNF MCDU should display the F-PLN page to allow the pilot to monitor time, speed and altitude predictions. This page also displays matched or missed information for constraints.

CHECK vertical mode CLB if NAV is engaged.
CHECK vertical mode OP CLB if HDG/TRK is engaged.

MONITORING THE ND (ROSE NAV OR ARC)

Displays the lateral and vertical paths, in the current AP/FD active modes.

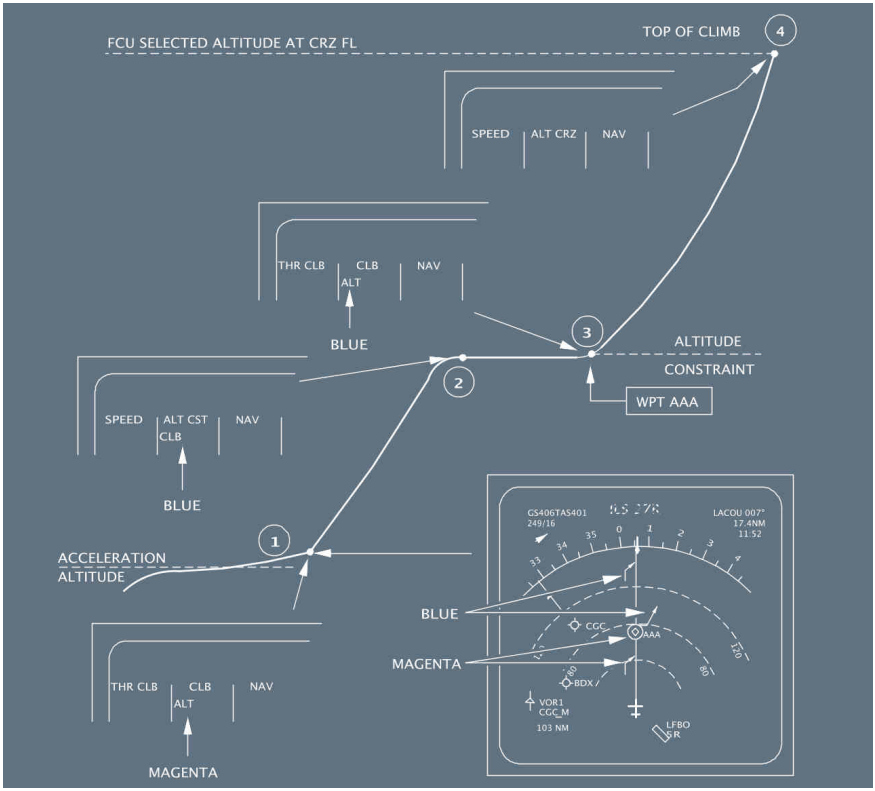


MONITORING THE AP/FD MODES AND FMA

If CLB mode is engaged, the flight mode annunciator (FMA) and the navigation display (ND) show the tactical situation as follows:

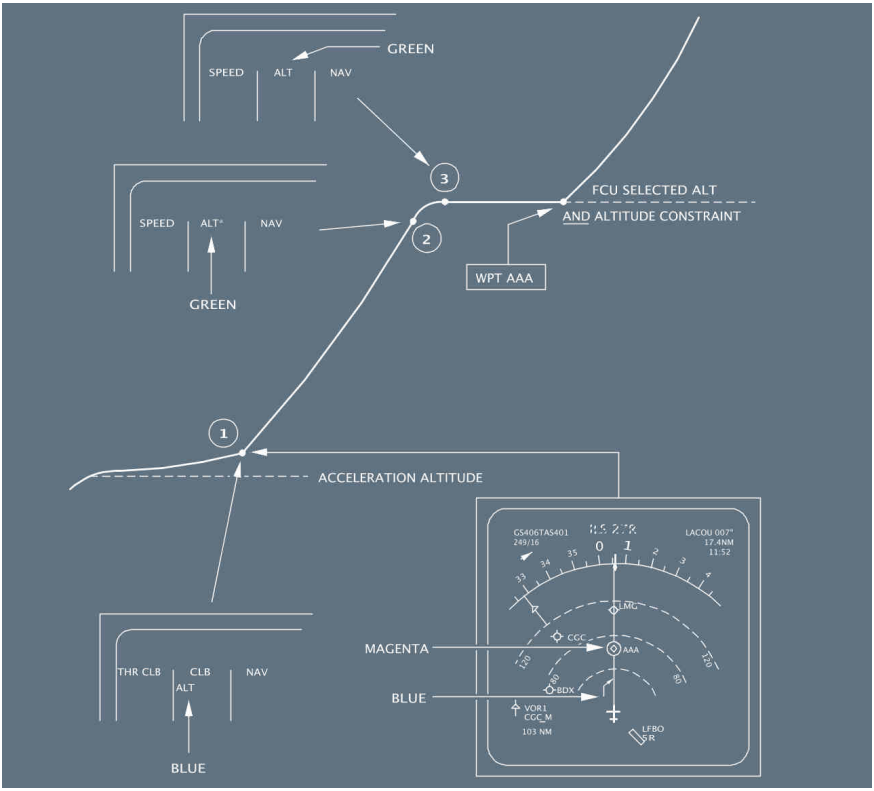
CASE 1

The FCU selected altitude is set above the next altitude constraint



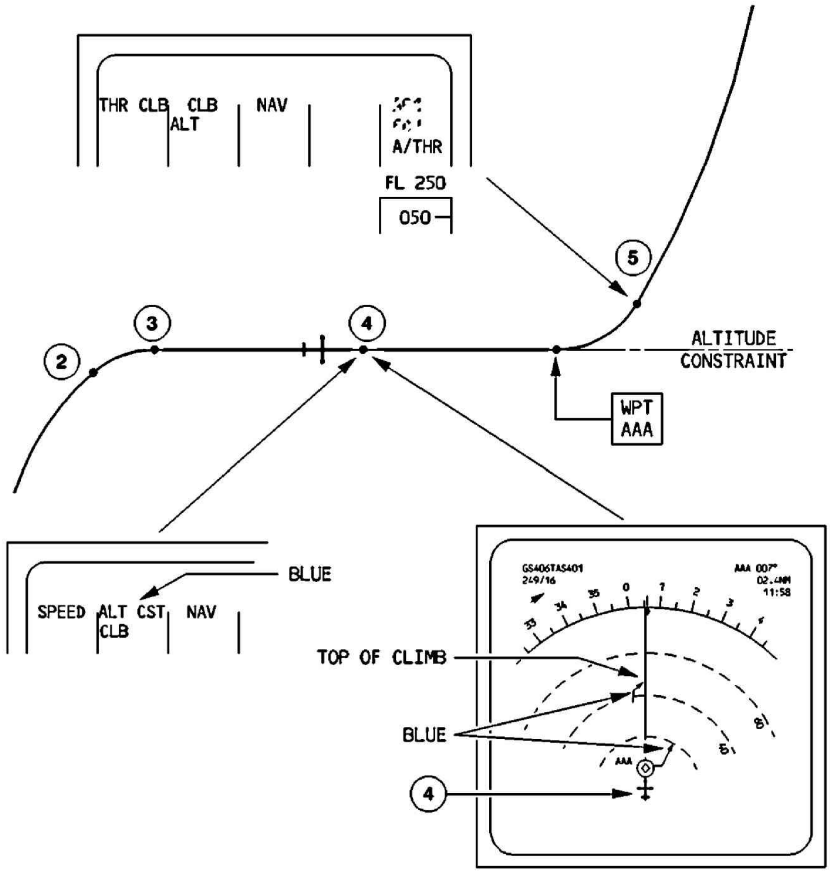
CASE 2

The FCU selected altitude is set at the next altitude constraint
The aircraft will automatically levels off at this altitude.



To resume the climb automatically when the waypoint AAA is reached, apply the following procedure during the level off (Position 4):

SELECT the FCU altitude to the next constraint (if any) or the cruise FL.
PUSH the FCU ALT selector knob to arm CLB mode.



RECOMMENDATION:

To ensure that you will not miss the next constraint, it is recommended to select the FCU altitude to the next constraint as described above.

MONITORING THE CONSTRAINTS

SPEED, ALTITUDE and TIME constraint can be checked using MCDUs. Each constraint is preceded by a star that indicates if the constraint is matched (magenta star) or missed (amber star).

ALTITUDE CONSTRAINT

- **If an altitude constraint is predicted as missed,** use the following procedure:

  SET the FCU ALT to the next ALT CSTR
  CHECK the position of the level off symbol on the ND (blue arrow) with respect to the waypoint with the constraint.
  DECREASE the target speed until the constraint is met.

SPEED CONSTRAINT

CHECK the SPD CSTR predictions on the MCDU.

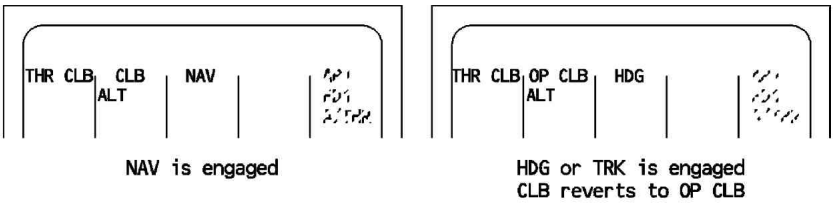
A magenta or amber star (*) indicates that the aircraft will match or miss the constraint.
If the aircraft is to miss the constraint by more than 10 kt, the MCDU scratchpad displays "SPD ERROR AT WPT ---- ".

"CHECK GW"MESSAGE.

Refer to PRO-SUP-22-10 Other Abnormal Procedures - CHECK GW Message

HDG/TRK MODE ENGAGEMENT

- **If HDG/TRK is engaged,** the guidance does not consider any F-PLN constraint. Therefore if the flight crew disengages NAV, CLB mode reverts to OP CLB.



SPEED SELECTION

- **If a specific speed is required:**
  TURN and PULL the SPD selector knob. (This changes the target speed to blue on the PFD speed scale).
  Predictions on the F-PLN page assume that the speed remains selected until the next SPD LIM or SPD CSTR, or the next phase, whichever comes first.

MONITORING THE CLIMB PHASE

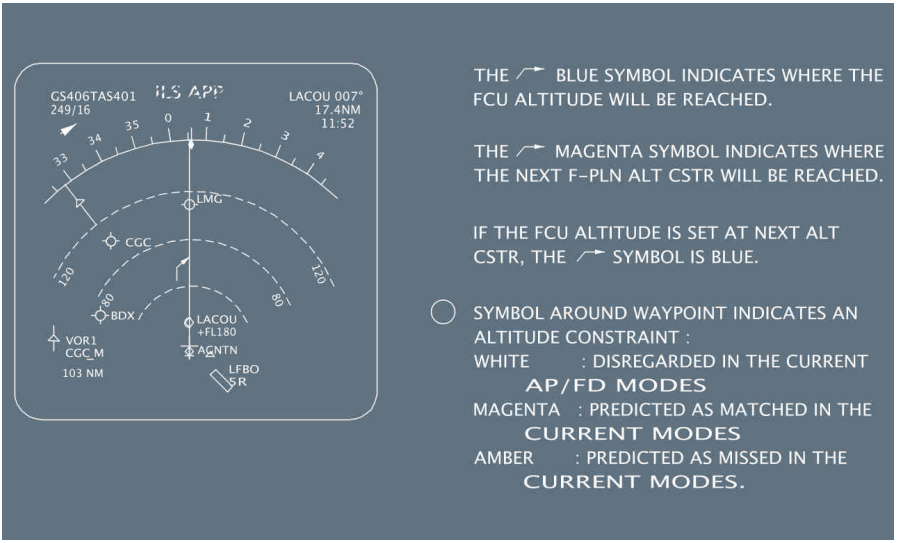
Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

The PF MCDU should display the PERF CLB page allowing him to monitor the climb.
The PNF MCDU should display the F-PLN page to allow the pilot to monitor time, speed and altitude predictions. This page also displays matched or missed information for constraints.

CHECK vertical mode CLB if NAV is engaged.
CHECK vertical mode OP CLB if HDG/TRK is engaged.

MONITORING THE ND (ROSE NAV OR ARC)

Displays the lateral and vertical paths, in the current AP/FD active modes.

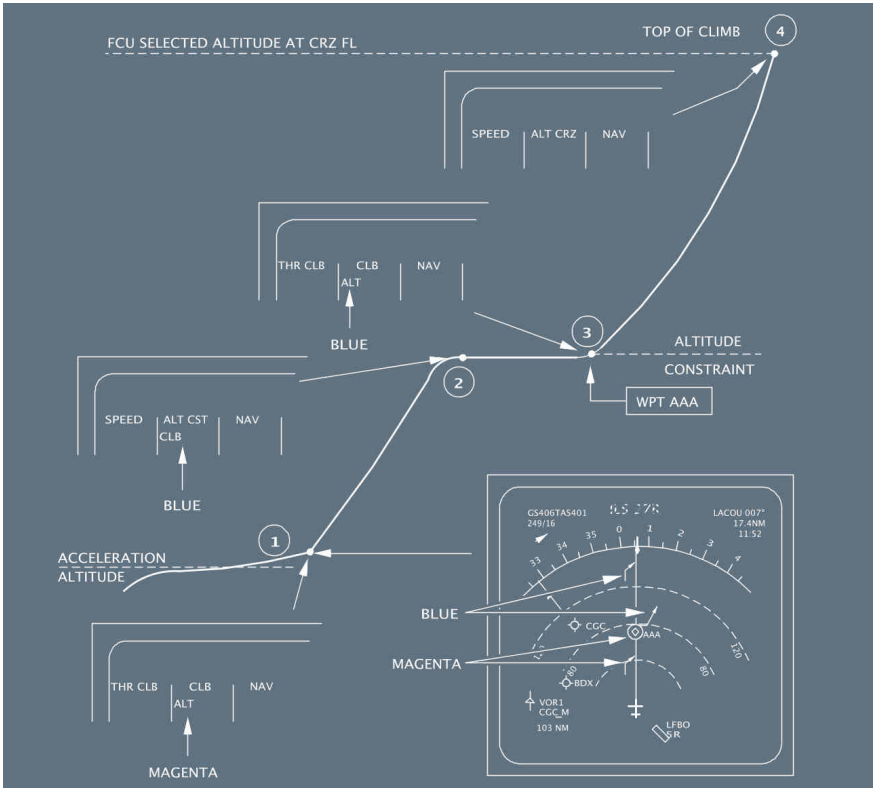


MONITORING THE AP/FD MODES AND FMA

If CLB mode is engaged, the flight mode annunciator (FMA) and the navigation display (ND) show the tactical situation as follows:

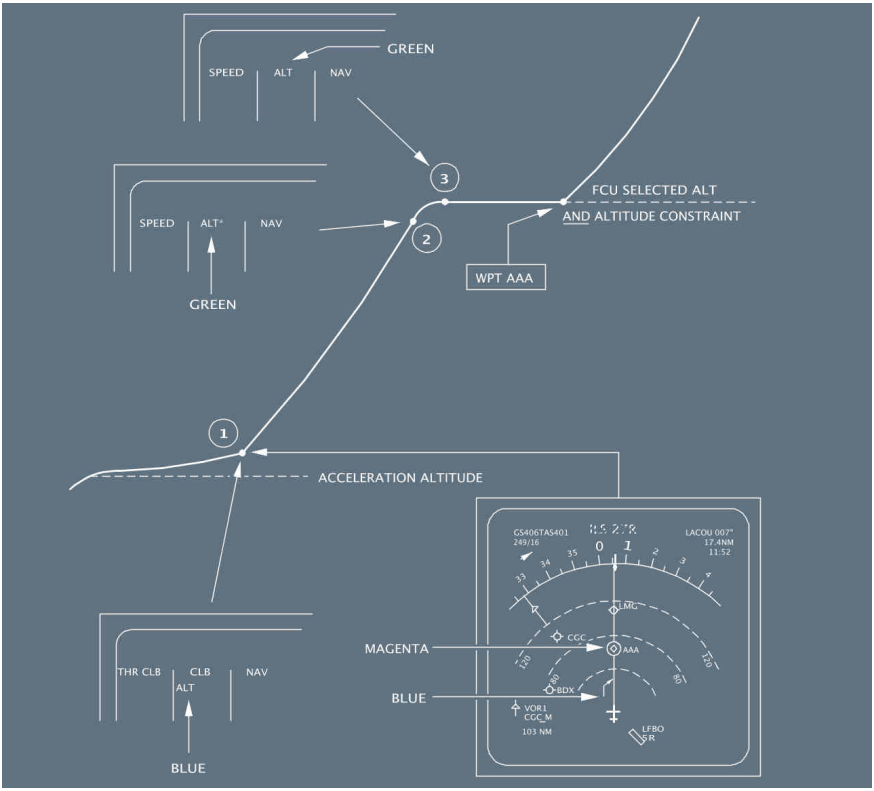
CASE 1

The FCU selected altitude is set above the next altitude constraint



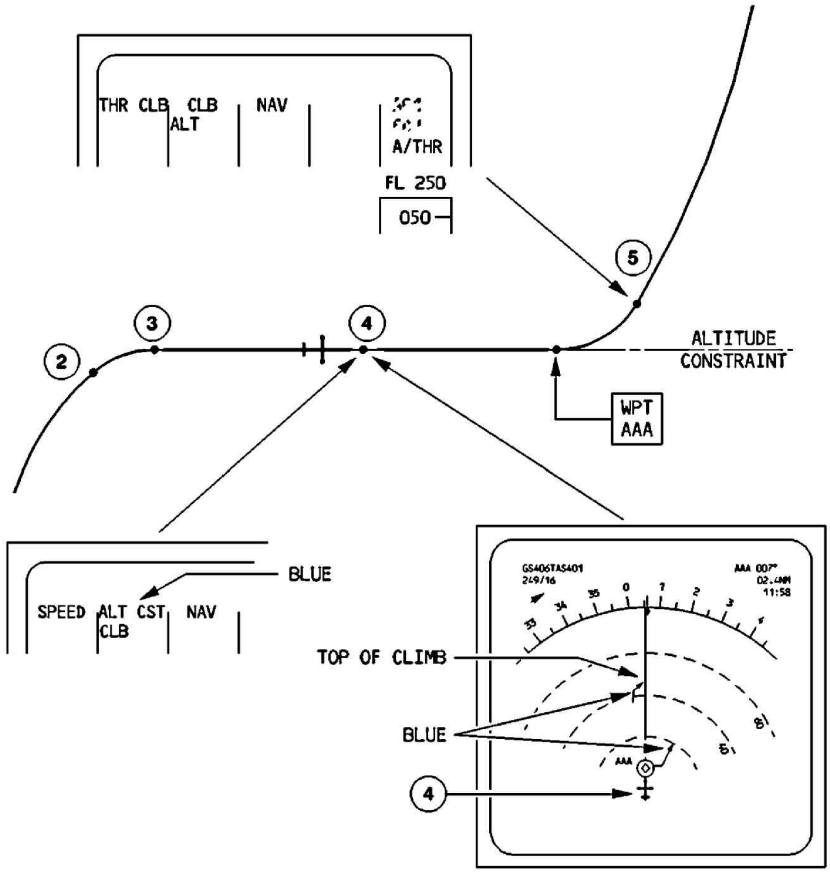
CASE 2

The FCU selected altitude is set at the next altitude constraint
The aircraft will automatically levels off at this altitude.



To resume the climb automatically when the waypoint AAA is reached, apply the following procedure during the level off (Position 4):

SELECT the FCU altitude to the next constraint (if any) or the cruise FL.
PUSH the FCU ALT selector knob to arm CLB mode.



RECOMMENDATION:

To ensure that you will not miss the next constraint, it is recommended to select the FCU altitude to the next constraint as described above.

MONITORING THE CONSTRAINTS

SPEED, ALTITUDE and TIME constraint can be checked using MCDUs. Each constraint is preceded by a star that indicates if the constraint is matched (magenta star) or missed (amber star).

ALTITUDE CONSTRAINT

- **If an altitude constraint is predicted as missed,** use the following procedure:

  SET the FCU ALT to the next ALT CSTR
  CHECK the position of the level off symbol on the ND (blue arrow) with respect to the waypoint with the constraint.
  DECREASE the target speed until the constraint is met.

SPEED CONSTRAINT

CHECK the SPD CSTR predictions on the MCDU.

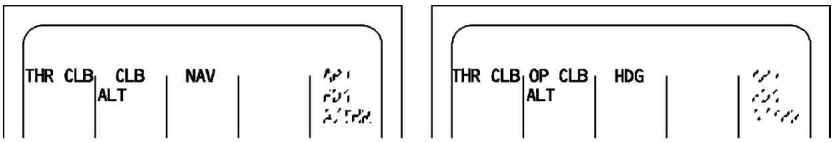
A magenta or amber star (*) indicates that the aircraft will match or miss the constraint.
If the aircraft is to miss the constraint by more than 10 kt, the MCDU scratchpad displays "SPD ERROR AT WPT ---- ".

"CHECK GW" MESSAGE.

Refer to PRO-SUP-22-10 Other Abnormal Procedures - CHECK GW Message

HDG/TRK MODE ENGAGEMENT

- **If HDG/TRK is engaged,** the guidance does not consider any F-PLN constraint. Therefore if the flight crew disengages NAV, CLB mode reverts to OP CLB.



NAV is engaged

HDG or TRK is engaged
CLB reverts to OP CLB

SPEED SELECTION

- **If a specific speed is required:**
  TURN and PULL the SPD selector knob. (This changes the target speed to blue on the PFD speed scale).
  Predictions on the F-PLN page assume that the speed remains selected until the next SPD LIM or SPD CSTR, or the next phase, whichever comes first.

MONITORING THE CLIMB PHASE

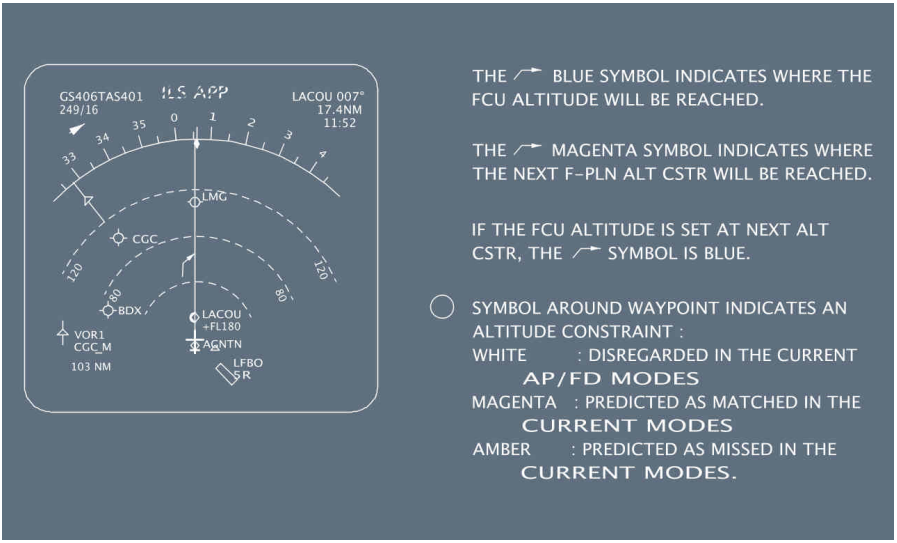
Applicable to: B-HSQ, B-HSR

The PF MCDU should display the PERF CLB page allowing him to monitor the climb.
The PNF MCDU should display the F-PLN page to allow the pilot to monitor time, speed and altitude predictions. This page also displays matched or missed information for constraints.

CHECK vertical mode CLB if NAV is engaged.
CHECK vertical mode OP CLB if HDG/TRK is engaged.

MONITORING THE ND (ROSE NAV OR ARC)

Displays the lateral and vertical paths, in the current AP/FD active modes.

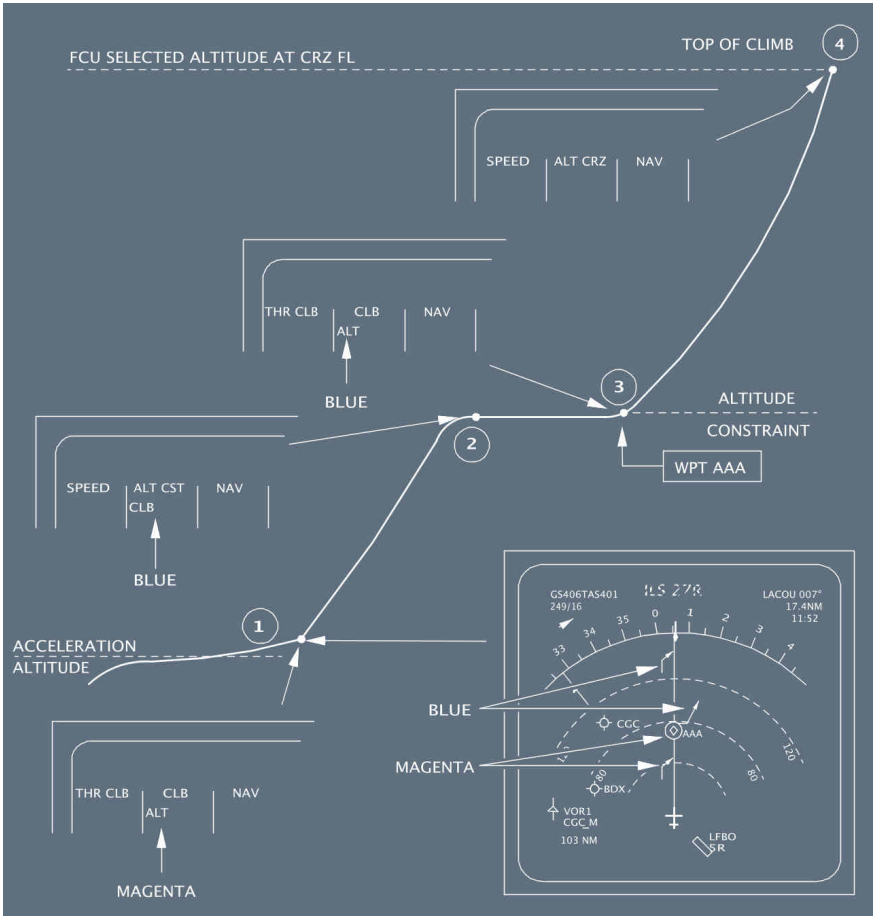


MONITORING THE AP/FD MODES AND FMA

If CLB mode is engaged, the flight mode annunciator (FMA) and the navigation display (ND) show the tactical situation as follows:

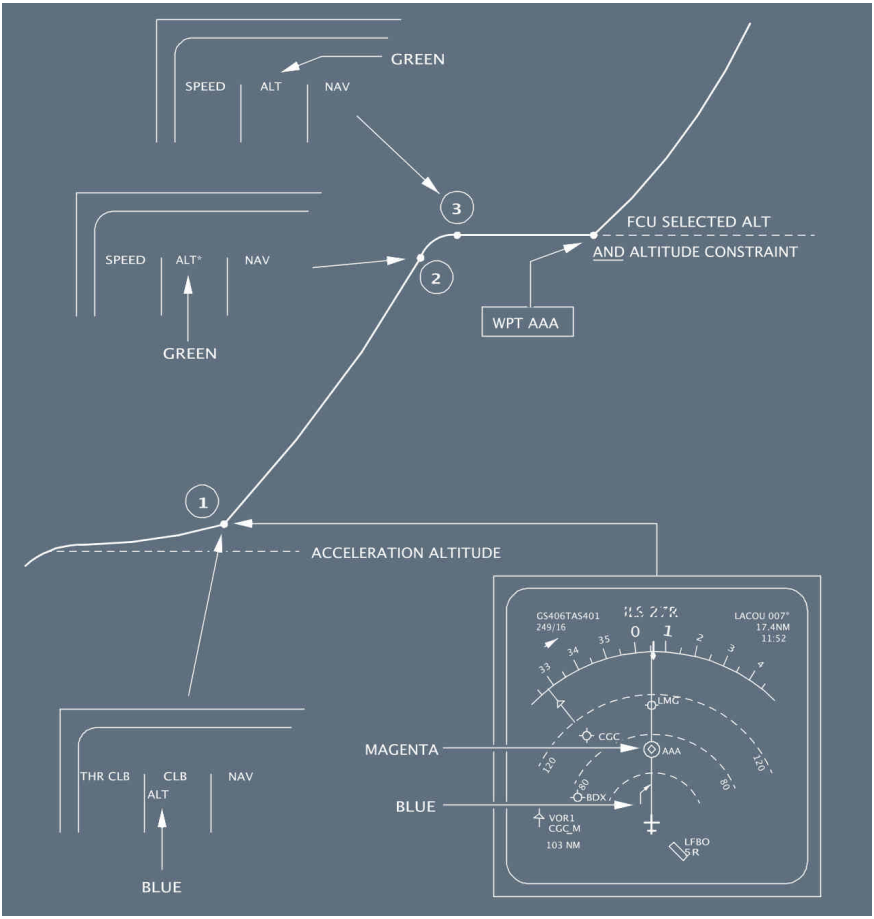
CASE 1

The FCU selected altitude is set above the next altitude constraint



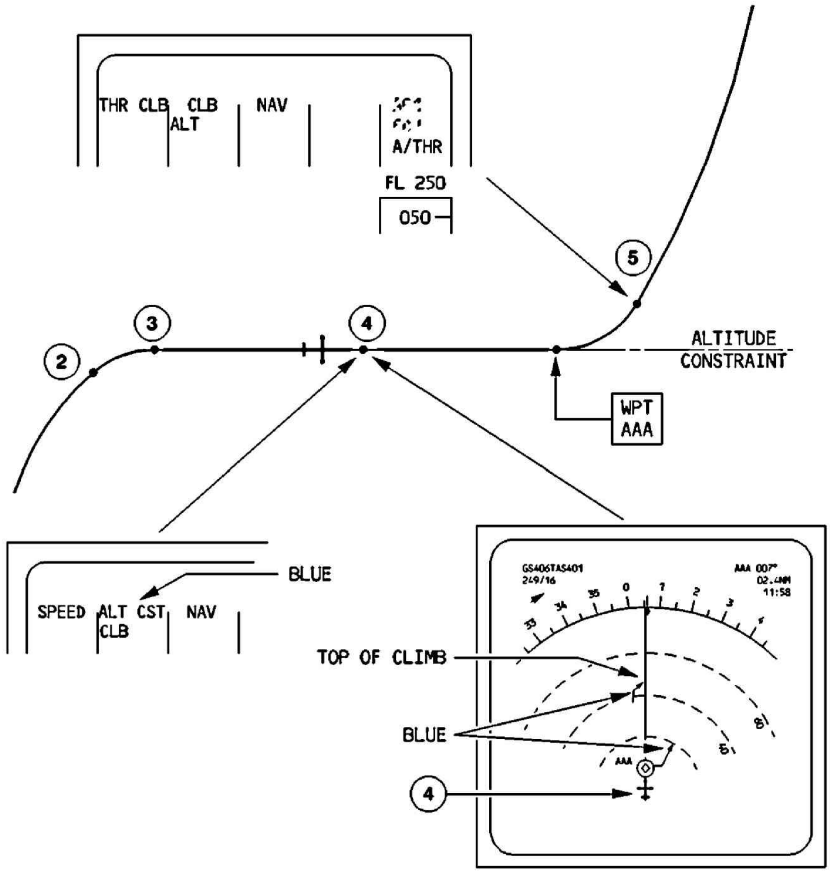
CASE 2

The FCU selected altitude is set at the next altitude constraint
The aircraft will automatically levels off at this altitude.



To resume the climb automatically when the waypoint AAA is reached, apply the following procedure during the level off (Position 4):

SELECT the FCU altitude to the next constraint (if any) or the cruise FL.
PUSH the FCU ALT selector knob to arm CLB mode.



RECOMMENDATION:

To ensure that you will not miss the next constraint, it is recommended to select the FCU altitude to the next constraint as described above.

MONITORING THE CONSTRAINTS

SPEED, ALTITUDE and TIME constraint can be checked using MCDUs. Each constraint is preceded by a star that indicates if the constraint is matched (magenta star) or missed (amber star).

ALTITUDE CONSTRAINT

- **If an altitude constraint is predicted as missed,** use the following procedure:

  SET the FCU ALT to the next ALT CSTR
  CHECK the position of the level off symbol on the ND (blue arrow) with respect to the waypoint with the constraint.
  DECREASE the target speed until the constraint is met.

SPEED CONSTRAINT

CHECK the SPD CSTR predictions on the MCDU.

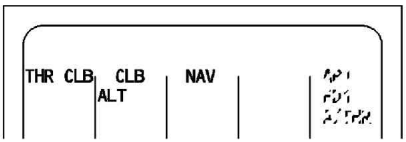
A magenta or amber star (*) indicates that the aircraft will match or miss the constraint.
If the aircraft is to miss the constraint by more than 10 kt, the MCDU scratchpad displays "SPD ERROR AT WPT ---- ".

"CHECK WEIGHT" MESSAGE.

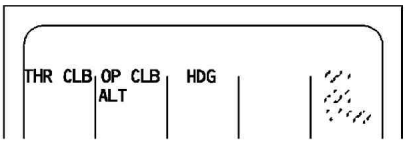
Refer to PRO-SUP-22-10 Other Abnormal Procedures - CHECK WEIGHT Message

HDG/TRK MODE ENGAGEMENT

- **If HDG/TRK is engaged,** the guidance does not consider any F-PLN constraint. Therefore if the flight crew disengages NAV, CLB mode reverts to OP CLB.



NAV is engaged



HDG or TRK is engaged
CLB reverts to OP CLB

SPEED SELECTION

- **If a specific speed is required:**
  TURN and PULL the SPD selector knob. (This changes the target speed to blue on the PFD speed scale).
  Predictions on the F-PLN page assume that the speed remains selected until the next SPD LIM or SPD CSTR, or the next phase, whichever comes first.

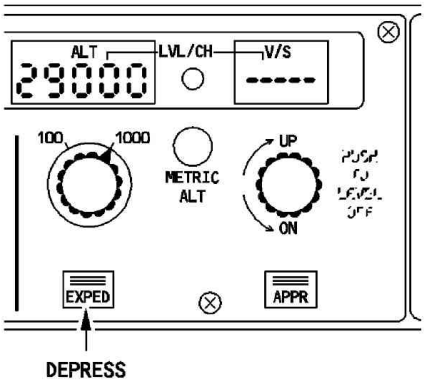
EXPEDITE CLIMB

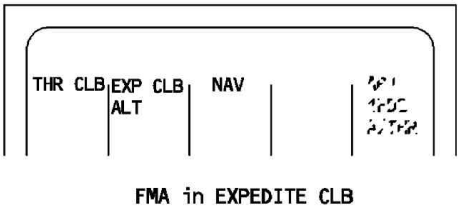
Applicable to: B-HSQ, B-HSR

The flight may use the expedite mode temporarily to clear a specified altitude or to match a constraint.

PRESS EXPED pb on the FCU.

The AP acquires and maintains Green Dot speed. There is no benefit to use expedite mode above FL 250. The mach corresponding to green dot is too low to maintain an increased vertical speed.





To revert to normal climb:
PUSH ALT knob CLB mode will engage.

Note: *Pulling ALT knob or V/S knob or SPD/MACH knob also disengages EXPEDITE. PRESSING EXPED pb never disengages the mode.*

IMMEDIATE RETURN TO ORIGIN AIRPORT

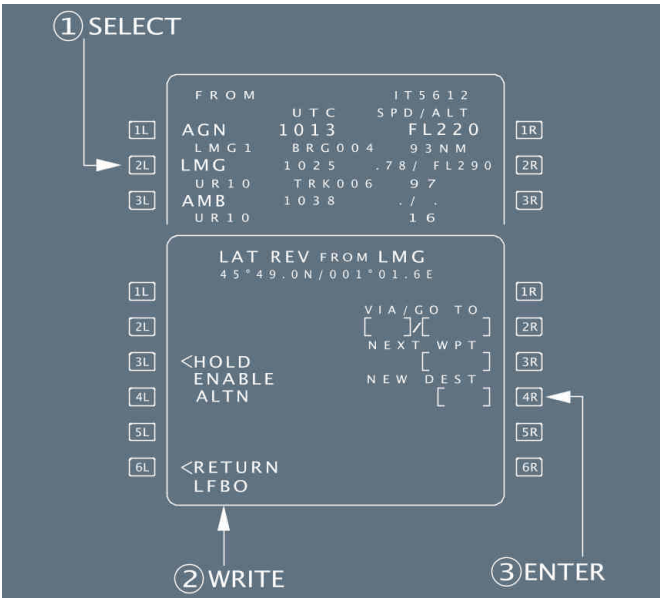
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

■ **If the SEC F-PLN has been prepared for an immediate return to the airport of origin:**

ACTIVATE the SEC F-PLN.

PERFORM a DIR TO the appropriate waypoint.

■ **If the SEC F-PLN has not been prepared for an immediate return to the airport of origin:**



PERFORM a lateral revision at TO waypoint

ENTER the departure airport ident in the NEW DEST field and INSERT the temporary flight plan.

PERFORM a lateral revision at the new destination

SELECT: APPR –STAR –VIA – TRANS and INSERT

● **When cleared to divert:**

PERFORM a DIR TO the suitable waypoint.

ENTER QNH, WIND, MDA/MDH, LDG CONF.

CHECK RAD NAV page.

IMMEDIATE RETURN TO ORIGIN AIRPORT

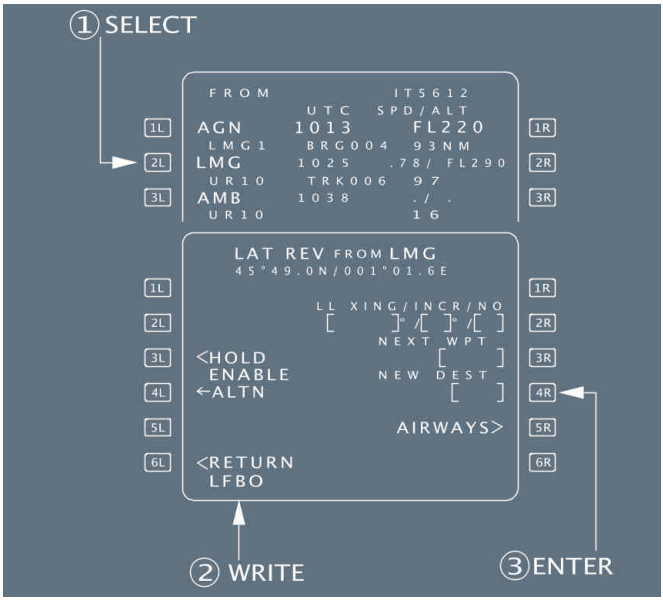
Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

■ **If the SEC F-PLN has been prepared for an immediate return to the airport of origin:**

ACTIVATE the SEC F-PLN.

PERFORM a DIR TO the appropriate waypoint.

■ **If the SEC F-PLN has not been prepared for an immediate return to the airport of origin:**



PERFORM a lateral revision at TO waypoint
ENTER the departure airport ident in the NEW DEST field and INSERT the temporary flight plan.
PERFORM a lateral revision at the new destination
SELECT: APPR –STAR –VIA – TRANS and INSERT

● **When cleared to divert :**

PERFORM a DIR TO the suitable waypoint.

ENTER QNH, WIND, MDA/MDH, LDG CONF.

CHECK RAD NAV page.

IMMEDIATE RETURN TO ORIGIN AIRPORT

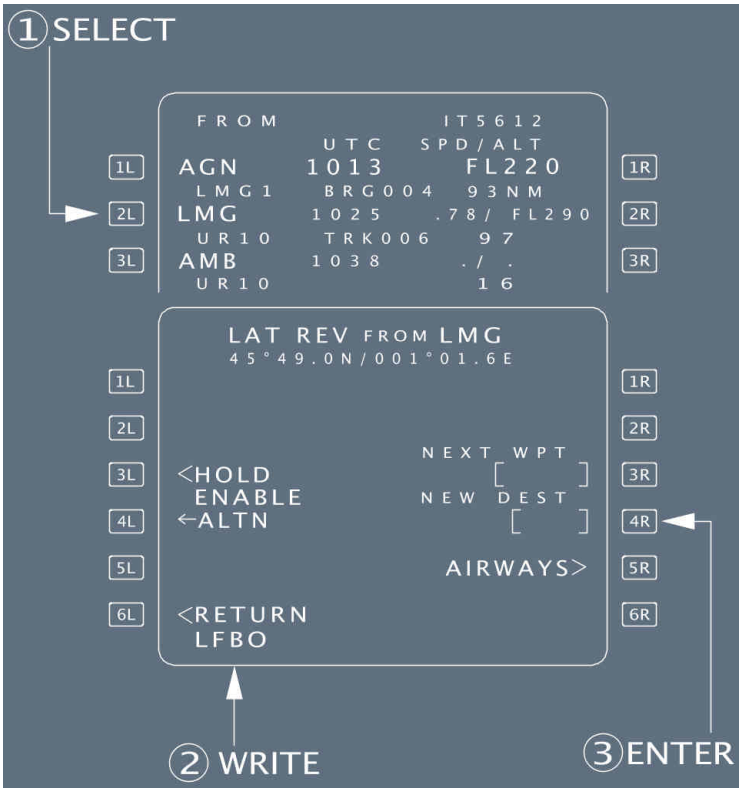
Applicable to: B-HSQ, B-HSR

■ **If the SEC F-PLN has been prepared for an immediate return to the airport of origin:**

REVERT to HDG mode, then ACTIVATE the SEC F-PLN.

PERFORM a DIR TO the appropriate waypoint.

■ **If the SEC F-PLN has not been prepared for an immediate return to the airport of origin:**



PERFORM a lateral revision at TO waypoint

ENTER the departure airport ident in the NEW DEST field.

PERFORM a lateral revision at the new destination

SELECT: APPR –STAR –VIA – TRANS and INSERT

CHECK and INSERT the TMPY F-PLN or continue with next revision.

■ **When cleared to divert :**

PERFORM a DIR TO the suitable waypoint.

ENTER QNH, WIND, MDA/MDH, LDG CONF.

CHECK RAD NAV page.

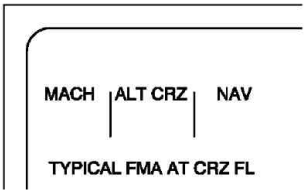
Intentionally left blank

Cruise

REACHING CRUISE FLIGHT LEVEL

Applicable to: ALL

On reaching the cruise flight level, the flight crew should be sure that the FMA displays “ALT CRZ”in its second column, which ensures that the aircraft is at cruise flight level and at Economy Cruise Mach (ECON CRZ MACH).



TYPICAL FMA AT CRZ FL

The FMGS engages the “soft altitude” (SOFT ALT) mode 2 min after the cruise flight level is captured and Mach stabilized. (SOFT ALT) mode allows the aircraft to deviate ± 50 ft from the target altitude to minimize the thrust variation and reduce the fuel consumption.

- **If the FMA does not display ALT CRZ at the assigned flight level,** soft altitude mode will not engage and the predictions will be computed at the preplanned flight level. This will occur when the ATC assigned flight level is lower than the preplanned flight level entered on the PROG page.

- **If the FMA does not display ALT CRZ at the assigned FL (as may occur when the ATC-assigned FL is lower than the preplanned FL selected initially):**

  PRESS the [PROG].

  ENTER the current cruise flight level.

  Note: If the current cruise flight level is above the preplanned FL, selecting the FCU updates it automatically.

“SET SPD AUTO” (OR “SET MANAGED SPD”)

- **If the climb phase was flown in selected speed and if the cruise phase is planned to be flown in managed speed (ECON MACH/SPEED)** , “SET SPD AUTO” (or “SET MANAGED SPEED”) appears on the PFD and MCDU as a reminder.

PRESS the FCU speed selector knob to activate the managed Mach.

MONITORING THE NAVIGATION ACCURACY

Applicable to: ALL

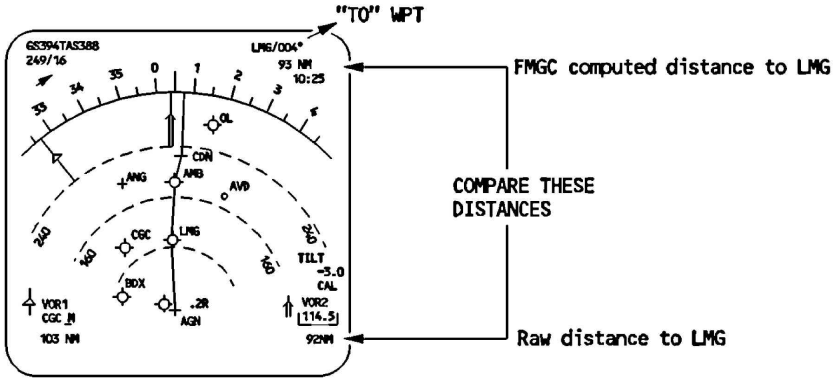
GENERAL

On aircraft equipped with GPS PRIMARY, the navigation accuracy check is not required as long as GPS PRIMARY ◁ is available.
Otherwise, navigation accuracy shall be checked periodically in cruise.

The PROG page displays an estimated accuracy as being high or low (center of sixth line):
- "HIGH" means that the FMGS estimates the FM position accurate enough to meet the EN ROUTE criteria
- "LOW" means that the pilot must compare raw data from tuned navaids with corresponding data computed by FM and shown on the ND or MCDU PROG page. The appearance of the message "NAV ACCUR DOWNGRAD" on the MCDU calls for a similar crosscheck.

Note: *The pilot should make such a comparison periodically, even if the PROG page is displaying "HIGH" and navaids are available: this allows him to quantify the FM position error.*

The method for checking the accuracy is explained in the SOP and in Evaluation of position accuracy chapter (*Refer to DSC-22_20-20-20 General*).
A quick check is explained here below when the TO waypoint is a DME type. (VOR/DME or VOR/TAC or DME or TAC)



Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

POSITION DISCREPANCY

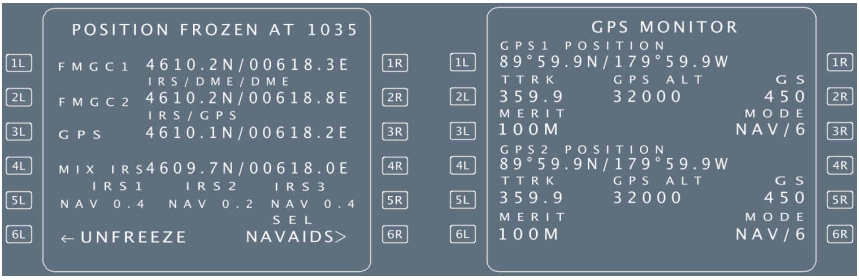
- **If there is a discrepancy between the raw data position and the FM position:**

  PRESS the DATA key on the MCDU.

  SELECT the POSITION MONITOR page.

  SELECT "FREEZE".

  On the other MCDU: Select the GPS MONITOR page.



Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

POSITION DISCREPANCY

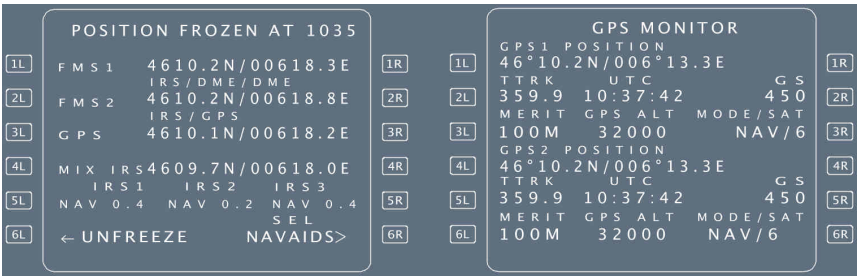
- **If there is a discrepancy between the raw data position and the FM position:**

  PRESS the DATA key on the MCDU.

  SELECT the POSITION MONITOR page.

  SELECT "FREEZE".

  On the other MCDU : Select the GPS MONITOR page.



Applicable to: B-HSQ, B-HSR

POSITION DISCREPANCY

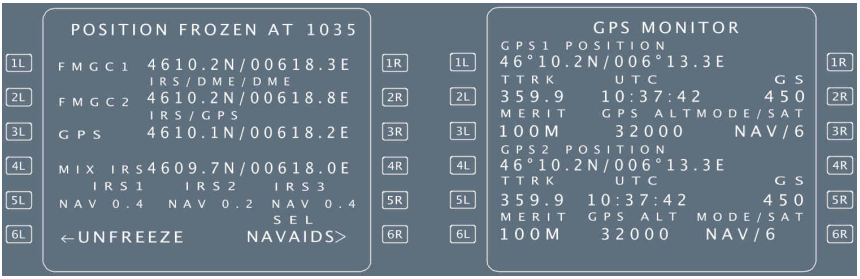
- **If there is a discrepancy between the raw data position and the FM position:**

  PRESS the DATA key on the MCDU.

  SELECT the POSITION MONITOR page.

  SELECT "FREEZE".

  On the other MCDU: Select the GPS MONITOR page.



MONITORING THE FUEL PREDICTIONS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The F-PLN and FUEL PRED pages display fuel and time predictions throughout the flight. These predictions are meaningful if the lateral and vertical flight plan, and the entered winds are accurate enough.

PROCEDURE

UPDATE the F-PLN to show accurate predictions.
Periodically CHECK the wind on the F-PLN B page, and update it when the current wind is significantly different.

Monitor the fuel by checking:
- Estimated fuel on board (EFOB) at destination (F-PLN page)
- EFOB at alternate and extra fuel (FUEL PRED page)

- **If the extra fuel is negative, modify successively the following data until the extra fuel becomes null or positive:**

  CHECK current cruise flight level versus the optimum level (OPT FL)

  If advisable, REQUEST reassignment to the OPT FL (or OPT FL + 2 000)

  Decrease the cost index down to zero if necessary (MIN FUEL)

SELECT another ALTN on the ALTN page and CHECK whether or not XTRA FUEL becomes positive.

Continue to check different alternates until you find one for which XTRA FUEL is null or positive.

- **When an alternate is not necessary, you may select "NO ALTN"option:**

  CHECK the required conditions (weather, runways, etc.) for NO ALTN.

  SELECT "NO ALTN"on the ALTN selection page.

  ADJUST FINAL TIME on the FUEL PRED page.

  CHECK XTRA FUEL.

MONITORING THE FUEL PREDICTIONS

Applicable to: B-HSQ, B-HSR

The F-PLN and FUEL PRED pages display fuel and time predictions throughout the flight. These predictions are meaningful if the lateral and vertical flight plan, and the entered winds are kept accurate enough as the flight progresses.

PROCEDURE

In addition to the Fuel Management procedure described in the SOPs (*Refer to 00010288 **Not found***), periodically apply the following actions:

KEEP ACCURATE FMS PREDICTIONS

Periodically UPDATE the F-PLN elements (F-PLN waypoints, step altitudes, predicted winds).

CHECK the MIN DEST FOB value on the FUEL PRED page

The MIN DEST FOB value is computed by the FMS and by default it is equals to ALTN + FINAL. ALTN, FINAL and MIN DEST FOB can be modified by the flight crew.
At the beginning of the CRZ phase, and/or after any change of destination or alternate airport, check that the MIN DEST FOB value is meaningful. Otherwise, update the MIN DEST FOB value, as appropriate.

CHECK the DEST EFOB value on the F-PLN or FUEL PRED page

MONITOR the EFOB at destination on the F-PLN or FUEL PRED page. If necessary, ADAPT the flight strategy.

"DEST EFOB BELOW MIN"MESSAGE

If the predicted EFOB at destination becomes less than the MIN DEST FOB value displayed on the FUEL PRED page:

- The destination EFOB turns to amber on the F-PLN, FUEL PRED and PERF (CLB, CRZ, DES) pages, and REPORT page.
- The "DEST EFOB BELOW MIN"amber message is displayed on the MCDU scratchpad, after 2 min (if the FMS is in CRZ or DES phase).

Note: If the flight crew has cleared the "DEST EFOB BELOW MIN"message, and if the predicted EFOB at destination is still less than the MIN DEST FOB value, the "DEST EFOB BELOW MIN"message will appear again at the beginning of the descent phase.

PROCEDURE

● **If the "DEST EFOB BELOW MIN"message is triggered on the MCDU:**

CHECK the DEST EFOB value on the F-PLN or FUEL PRED page,

CHECK the hypothesis used by the FMS to compute the fuel predictions,

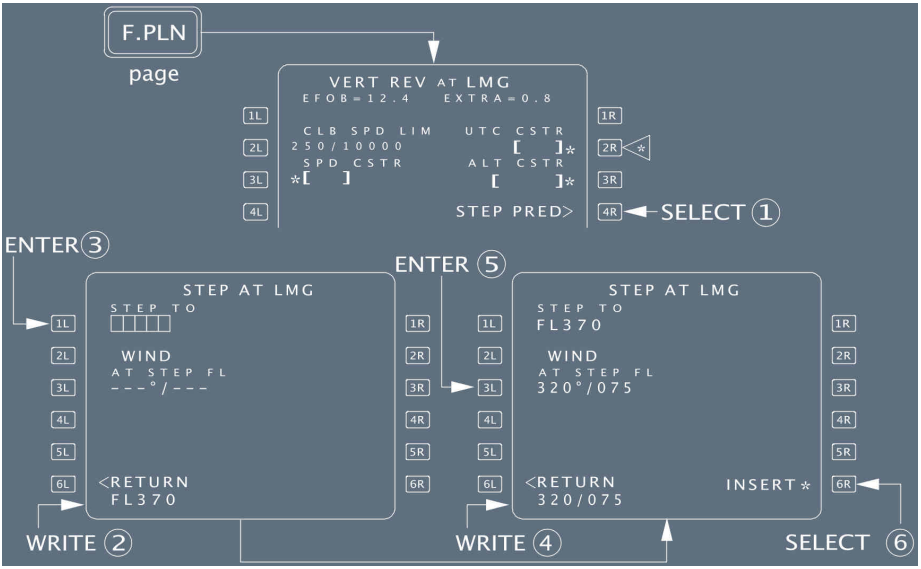
Check that the F-PLN elements (F-PLN waypoints, step altitudes, predicted winds) are up-to-date, to ensure that the FMS predictions are accurate.
Check that the MIN DEST FOB fuel value is meaningful and corresponds to the planned fuel strategy.

ADAPT the flight strategy as required.

ENTERING A STEP CLIMB OR A STEP DESCENT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

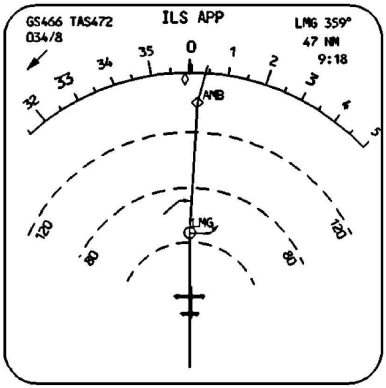
The flight crew can use the STEP PREDICTION page to enter one step climb or one step descent at any waypoint of the cruise phase except the "FROM" waypoint.

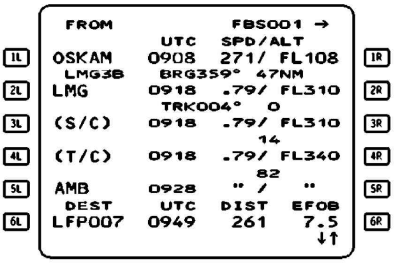


PROCEDURE

PRESS the F-PLN key.
SELECT "VERT REV"at the waypoint where you want to climb.
WRITE a step altitude into the scratchpad and ENTER it.
WRITE a wind (if it is significantly different from the initial cruise-flight-level wind) into the scratchpad and ENTER it.
INSERT the step.
CHECK the predictions.

The FM uses the step climb or the step descent to recompute the predictions.
The ND shows symbols for the start of climb (S/C) or descent and the top of climb (T/C) or bottom of descent. The MCDU shows the associated pseudo-waypoints.
The step automatically revises the cruise flight level.
The flight crew must initiate the climb or the descent by pulling out or pushing the altitude selector knob. CLB or OP CLB will engage in climb, DES or OP DES in descent.
DES mode engages with a constant vertical speed of -1 000 ft/min.
If the aircraft passes the step waypoint without beginning a climb or a descent, the system deletes the step from the vertical F-PLN automatically ("STEP DELETED" appears) and recomputes the predictions.
The system will not accept a step climb or descent if it does not ensure at least one minute of flight time at the new altitude.





If no step wind is entered, the wind used at the new CRZ FL is automatically defaulted to the wind at the previous flight level.

ENTERING A STEP CLIMB OR A STEP DESCENT

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

The crew may use the STEP ALTS page to enter up to four geographic step points or one optimal step (computed by the FMGS) at any waypoint of the cruise.

PROCEDURE

PRESS the PERF key.
SELECT "STEP ALTS" prompt.

The PERF PAGE displays this prompt in cruise phase. The crew may also call up the STEP ALTS page using a vertical revision at any cruise waypoint.

ENTERING AN OPTIMAL STEP (ONLY STEP CLIMB)

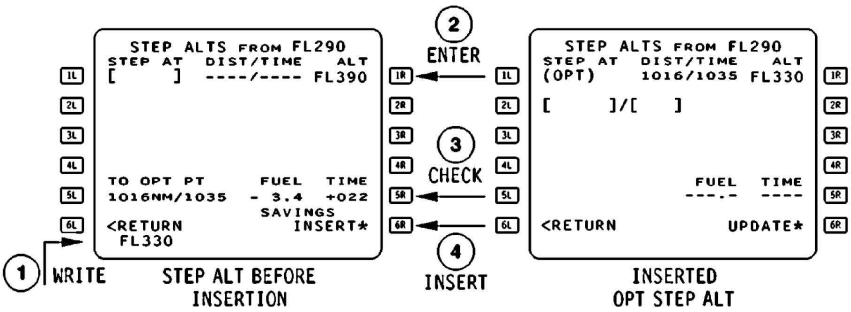
WRITE a step altitude or FL into the scratchpad.
ENTER the step altitude or FL in the [1R] field.
CHECK the FUEL and TIME SAVINGS predictions on the 5L and 5R fields.
PUSH the INSERT prompt [6R] if adequate.

After insertion, the optimum step climb is updated only when the flight crew presses the UPDATE prompt [6R].
The ND shows symbols for the start of climb (S/C) and the top of climb (T/C). The MCDU shows the associated pseudo-waypoints.
It is possible to convert an optimum step to a geographic step by overwriting the [1L] field (see geographic step).

- **When reaching the step climb pseudo-waypoint:**

  REQUEST climb clearance.

  ADJUST the FCU altitude to the STEP ALT, and PUSH.



ENTERING A GEOGRAPHIC STEP

WRITE a step altitude into the scratchpad.

The format is position/altitude (or FL). The position can be a waypoint or waypoint/distance to waypoint. The waypoint/distance is an along track offset waypoint.

ENTER it in [1L] to [4L] field.

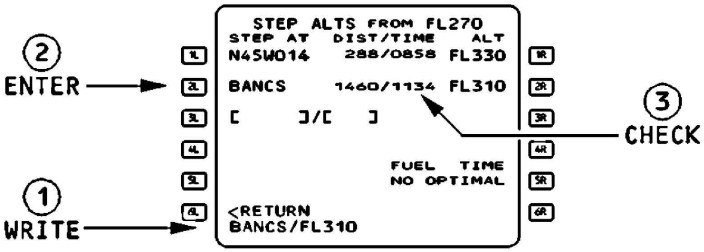
The entry of the initial geographic step point requires both a valid waypoint and altitude entries. When a step has been entered, the flight crew may change the position and the altitude independently. The flight crew cannot modify the position and the altitude in a single entry: To modify both, they should modify the position first, and then the altitude.

CHECK the predictions

- **When reaching the step climb or descent pseudo-waypoint (S/C or S/D):**

  REQUEST climb or descent clearance.

  ADJUST the FCU altitude to the STEP ALT, and PUSH.



INSERTED GEOGRAPHIC STEP ALT

The DIST/TIME field may display the following messages:
- ABOVE MAX if the step altitude exceeds the MAX ALT.
- IGNORED if the start step point is less than 50 nm from the top of descent.
- STEP NOW when the aircraft is within 20 nm of the step point.
  If the aircraft overflies the step waypoint without commencing a climb or a descent, the system deletes the step from the vertical F-PLN automatically (a “STEP DELETED” message is displayed on the MCDU scratchpad), and recomputes the predictions.
  A step is not deleted if the FCU altitude is moved only partially towards the step altitude.
  The flight phase remains “cruise” whenever a step is initiated.

Note: For an altitude restriction defined at a waypoint less than 50 nm before the top of descent and lower than the CRZ FL, it is recommended to enter an altitude constraint rather than a step.

ENTERING A STEP CLIMB OR A STEP DESCENT

Applicable to: B-HSQ, B-HSR

The crew may use the STEP ALTS page to enter up to four geographic step points or one optimal step (computed by the FMGS) at any waypoint of the cruise.

PROCEDURE

PRESS the F-PLN key on the MCDU.
SELECT the VERT REV page at any waypoint.
SELECT “STEP ALTS” prompt.

The PERF PAGE displays this prompt in cruise phase. The crew may also call up the STEP ALTS page using a vertical revision at any cruise waypoint.

ENTERING AN OPTIMAL STEP (ONLY STEP CLIMB)

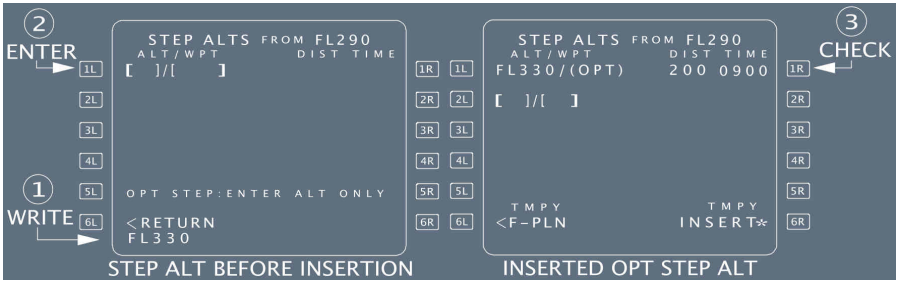
WRITE the desired step altitude into the scratchpad.

ENTER it in the [1L] field

The FMGS automatically computes the optimal location of the step and inserts it in the TMPY F-PLN.

CHECK the FUEL and TIME SAVINGS predictions on the [5R].

After insertion, the optimum step location is regularly updated, until the aircraft is within 20 nm of the step point.
The ND shows symbols for the start of climb (S/C) and the top of climb (T/C). The MCDU shows the associated pseudo-waypoints.
It is possible to convert an optimum step to a geographic step by overwriting the [1L] field (see geographic step).



- **When reaching the step climb pseudo-waypoint (S/C):**

  REQUEST climb clearance to ATC.

  ADJUST the FCU altitude to the STEP ALT, and PUSH the FCU knob.

Note: *The step will be deleted from the F-PLN after having sequenced the start of climb for the step.*

ENTERING A GEOGRAPHIC STEP (STEP CLIMB OR STEP DESCENT)

WRITE a step altitude and waypoint into the scratchpad.

The format is :
- *Altitude (or FL)/waypoint (Ex: FL 350/BERAD)*
- *Altitude (or FL)/waypoint/distance (Ex: FL 350/BERAD/-20)*

The waypoint must be in the flight plan.

ENTER it in [1L] to [4L] field.

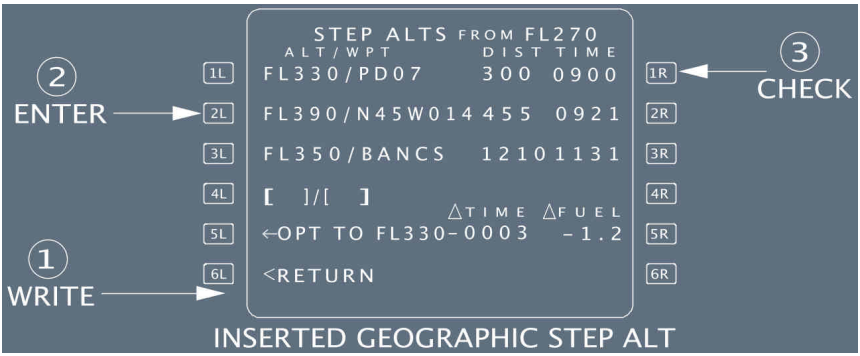
It is possible to independently modify either the location or the altitude of an existing step altitude. It is not possible to modify with a single entry both the location and the altitude : An entry "waypoint/xxx" will be taken by the system as an along track offset of xxx nautical miles.

CHECK the predictions (distance, time).

- **When reaching the step climb or descent pseudo-waypoint (S/C or S/D):**

  REQUEST climb or descent clearance

  ADJUST the FCU altitude to the STEP ALT, and PUSH the FCU knob.



The DIST/TIME field may display the following messages:

- ABOVE MAX if the step altitude exceeds the MAX ALT.
- IGNORED if the step end point is less than 50 nm from the top of descent or if the step climb is located prior to the top of climb or after the top of descent.
- STEP AHEAD when the aircraft is within 20 nm of the step point.
  If the aircraft overflies the step pseudo-waypoint without commencing a climb or a descent, the system deletes the step from the vertical F-PLN automatically (a “STEP DELETED” message is displayed on the MCDU scratchpad), and recomputes the predictions.
  The step is not deleted if the FCU altitude is moved only partially towards the step altitude.
  The flight phase remains “cruise” whenever a step is initiated.

Note: *For an altitude restriction defined at a waypoint less than 50 nm before the top of descent and lower than the CRZ FL, it is recommended to enter an altitude constraint rather than a step.*

IMMEDIATE CHANGE OF LEVEL IN CRUISE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

When the pilot changes his flight level without inserting a step:

- If the FCU-selected altitude is above the previous CRZ FL, the CRZ FL on the PROG page changes to the new flight level.
- If the FCU-selected altitude is lower than the previous CRZ FL and if the distance to DEST is more than 200 nm, the CRZ FL on the PROG page changes.

  In that case Mach target is managed as follows:
  - At the start of the descent, the Mach target is the managed Mach number at the initial cruise flight level.
  - When the aircraft reaches the new flight level, the Mach target switches either to the Mach number for the lower CRZ FL, or to the speed for the lower CRZ FL if the aircraft reaches the crossover altitude. This logic prevents the aircraft from exceeding VMO during descent.
- If the FCU-selected altitude is lower than the previous CRZ FL and the aircraft is within 200 nm of its destination, the system activates the descent phase.

The pilot may reactivate the cruise phase by entering a new cruise flight level in the PROG page.

IMMEDIATE CHANGE OF LEVEL IN CRUISE

Applicable to: B-HSQ, B-HSR

When the flight crew changes the flight level through a FCU altitude selection:

- If the FCU-selected altitude is above the previous CRZ FL, the CRZ FL on the PROG page changes to the new flight level.
- If the FCU-selected altitude is lower than the previous CRZ FL and if the distance to DEST is more than 200 nm, the CRZ FL on the PROG page changes.

  In that case Mach target is managed as follows:
  - At the start of the descent, the Mach target is the managed Mach number at the initial cruise flight level.
  - When the aircraft reaches the new flight level, the Mach target switches either to the Mach number for the lower CRZ FL, or to the speed for the lower CRZ FL if the aircraft reaches the crossover altitude. This logic prevents the aircraft from exceeding VMO during descent.
- If the FCU-selected altitude is lower than the previous CRZ FL and the aircraft is within 200 nm of its destination, the system activates the descent phase.

The pilot may reactivate the cruise phase by entering a new cruise flight level in the PROG page.

CAUTION	If the pilot modifies the CRZ FL on the PROG page without setting the FCU altitude, the FMS may target a Speed/Mach above VMO/MMO. Changing the FCU altitude makes the FMS behavior become correct again.

PREPARATION FOR DESCENT AND APPROACH

Applicable to: ALL

GENERAL

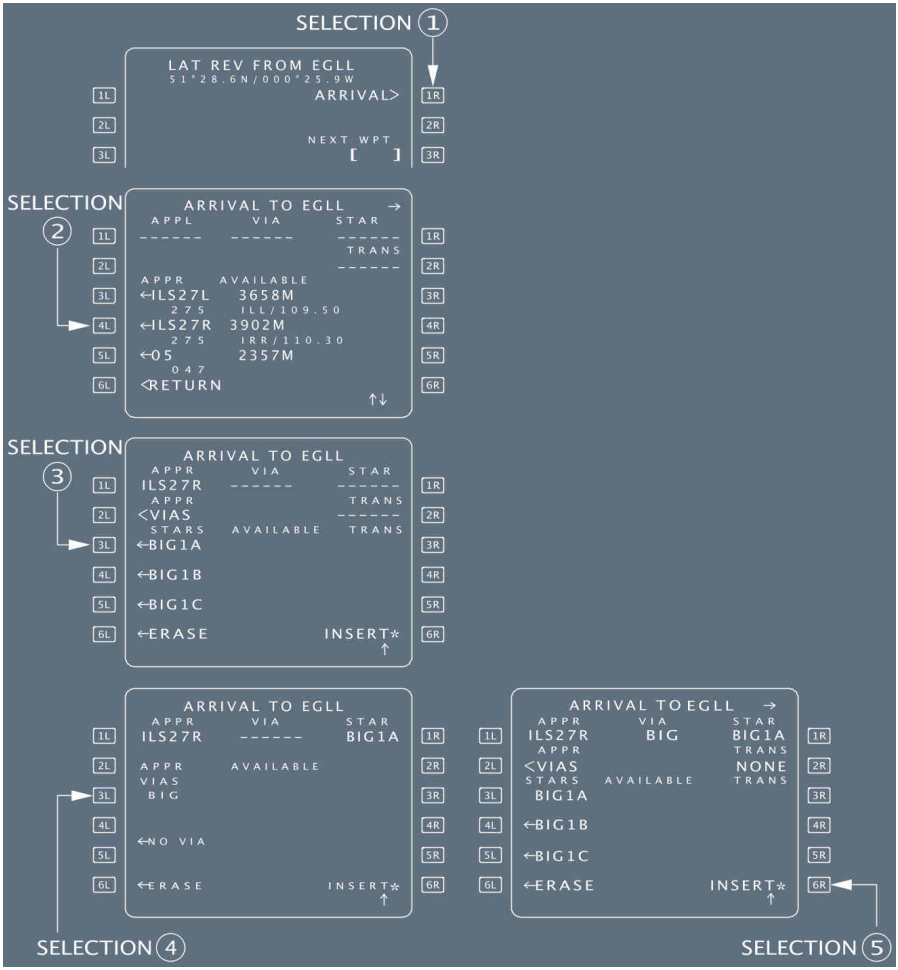
The preparation for descent and approach consists of :

- Entering PERF and WIND data
- Defining the lateral and vertical F-PLN
- Checking the tuning (auto or manual) of the appropriate navaids

After receiving the arrival information, the flight crew should use the following procedure.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

REVISION OF LATERAL F-PLN



PERFORM a lateral revision at destination
SELECT an ARRIVAL

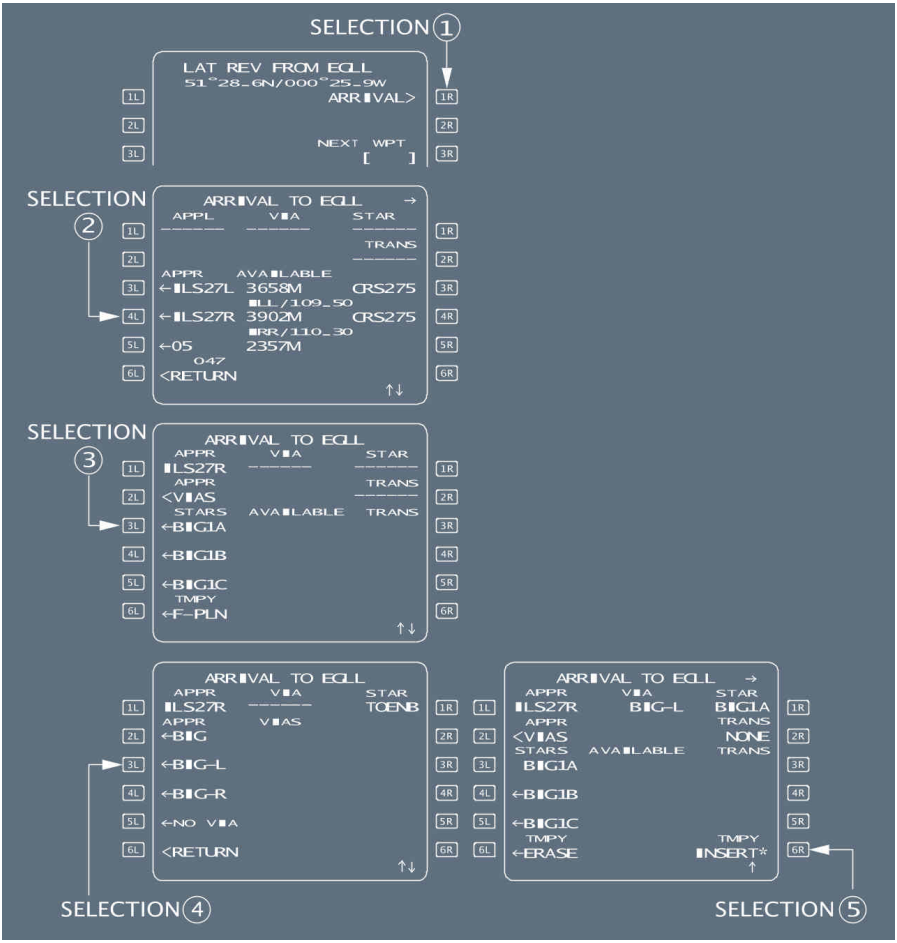
SELECT an APPROACH, a STAR, a TRANSITION, a VIA.

When the pilot selects successive items, the page are automatically sequenced. But pressing "NEXT PAGE" key brings up the APPR and STAR page successively.

CHECK the temporary revision including the missed approach.
INSERT the temporary revision, [6R] key.

Applicable to: B-HSQ, B-HSR

REVISION OF LATERAL F-PLN



PERFORM a lateral revision at destination
SELECT an ARRIVAL prompt.
SELECT an APPROACH.
SELECT A STAR.
If a desired, call up VIA subpage by pressing [2L] prompt on STAR page and SELECT a VIA.

Note: *When the pilot selects successive items, the page are automatically sequenced. But pressing "→" key brings up the APPR and STAR page successively.*

CHECK and INSERT the TMPY F-PLN or continue with next revision.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

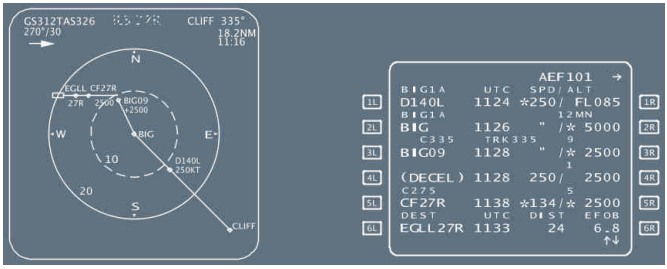
REVISION OF VERTICAL FLIGHT PLAN

CHECK that the speed and altitude constraints as displayed on the ND. (Use the CSTR pusbutton).
ENTER any additional speed or altitude constraints using the vertical revision page.

In order not to be too fast when commencing the approach, you may insert a speed constraint at the FAF (Final Approach Fix).
When all computations are completed.

REVIEW the flight plan, using the approach chart.

When the destination runway changes and if the previously selected STAR is compatible with the new runway, the system selects it automatically in the temporary F-PLN. If the flight crew has entered any revision or constraint on this STAR, it will not be transferred.
The pilot must reenter it in order to retain it for this approach.



Applicable to: B-HSQ, B-HSR

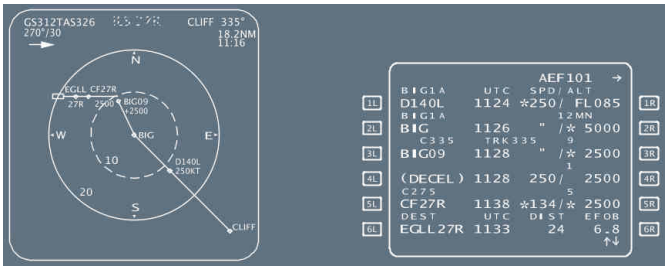
REVISION OF VERTICAL FLIGHT PLAN

CHECK that the speed and altitude constraints as displayed on the ND. (Use the CSTR pusbutton).
ENTER any additional speed or altitude constraints using the vertical revision page.

In order not to be too fast when commencing the approach, you may insert a speed constraint at the FAF (Final Approach Fix).
When all computations are completed.

REVIEW the flight plan, using the approach chart.

Note: *: When the crew changes the approach or the destination runway, and if the previously selected approach procedure is compatible with the new one, the system automatically inserts it in the temporary F-PLN.*
For further details, Refer to DSC-22_20-30-10-18 Changing the Departure/Arrival.



Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

ENTERING THE WINDS FOR DESCENT

Refer to DSC-22_20-30-20-20 Wind.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

ENTERING THE WINDS FOR DESCENT

Refer to DSC-22_20-30-20-25 Wind - Temperature - QNH - General.

Applicable to: B-HSQ, B-HSR

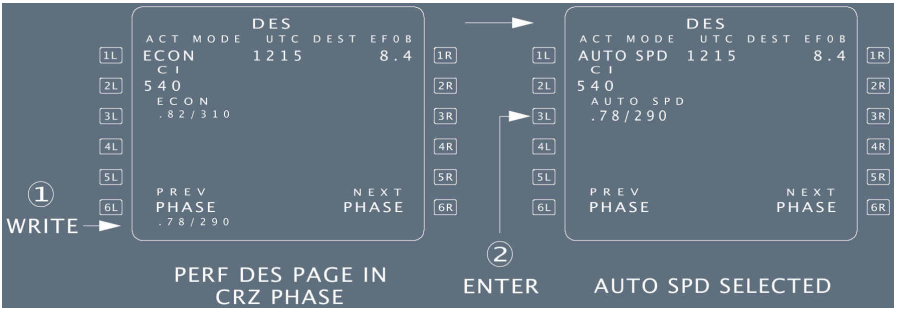
ENTERING THE WINDS FOR DESCENT

Refer to DSC-22_20-30-20-28 Wind - Temperature - QNH - General.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

ENTERING AN AUTO SPEED

As long as the descent phase is not active, the PERF DES page may either be used to select a speed, or a Mach number, or both, to replace the optimum descent speed. This speed is the called Auto speed.
The Flight Guidance Computer then uses your Auto speed instead of the ECON Speed for computing the descent profile and determining the Descent Managed Speed profile.
When the system switches to the descent phase, it sets the managed target speed to the auto speed. From there, you may modify the speed by using the FCU selector knob only.
Once in descent phase, the pilot cannot select the ECON speed again.



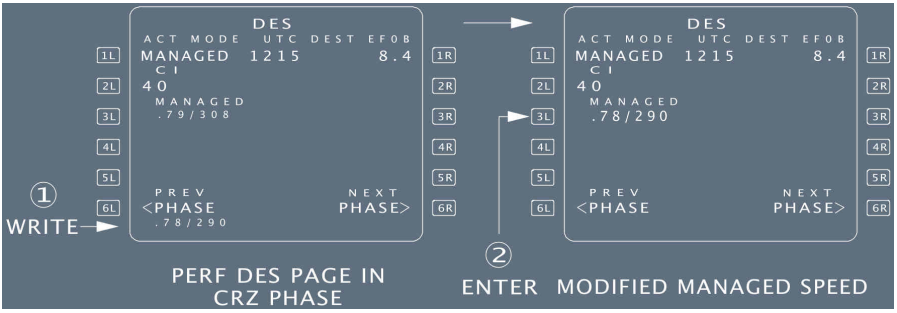
PROCEDURE

PRESS the PERF on MCDU.
SELECT the "NEXT PHASE" prompt.
WRITE the descent speed into the scratchpad and ENTER it.
The 3L Field Displays AUTO SPD Value.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

PRESELECTING A MANAGED SPEED/MACH

As long as the descent phase is not active, the PERF DES page may either be used to select a speed, or a Mach number, or both, to replace the optimum descent speed.
The Flight Guidance Computer then uses the entered speed, instead of the optimum speed for computing the descent profile.
When the system switches to the descent phase, it sets the MANAGED target speed to the entered speed. From there, the speed may only be modified by using the FCU selector knob.
Once in descent phase, the pilot cannot modify the MANAGED speed again.



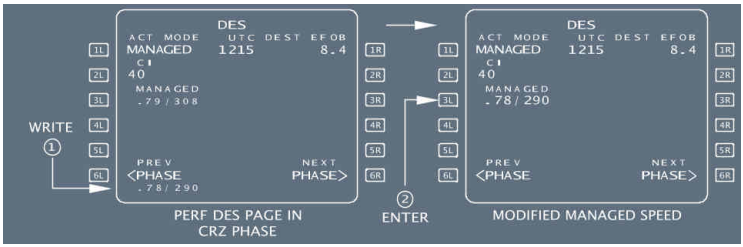
PROCEDURE

PRESS the PERF on MCDU.
SELECT the "NEXT PHASE" prompt.
WRITE the descent speed into the scratchpad and ENTER it.
The 3L field displays the imposed managed speed value.

Applicable to: B-HSQ, B-HSR

PRESELECTING A MANAGED SPEED/MACH

The PERF DES page may either be used to select a speed, or a Mach number, or both, to replace the optimum descent speed.
The Flight Guidance Computer then uses the entered speed, instead of the optimum speed for computing the descent profile.
When the system switches to the descent phase, it sets the MANAGED target speed to the entered speed. From there, the speed may only be modified by using the FCU selector knob.
Once in descent phase, the pilot cannot modify the MANAGED speed again.

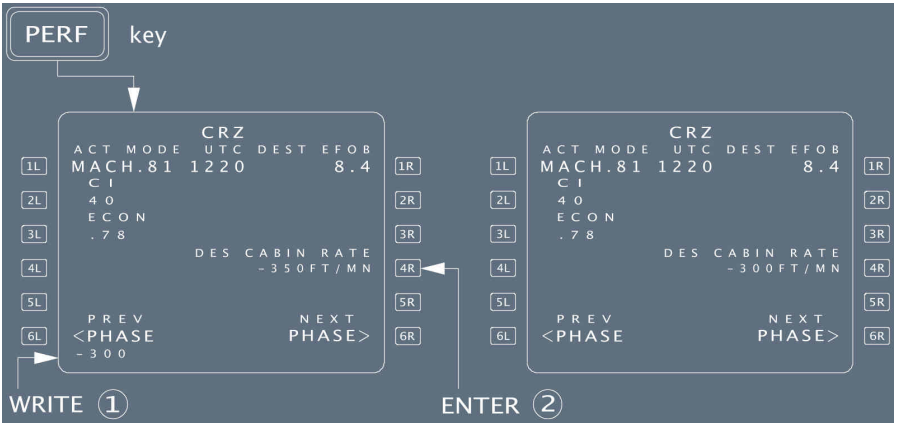


PROCEDURE

PRESS the PERF on MCDU.
SELECT the "NEXT PHASE" prompt.
WRITE the descent speed into the scratchpad and ENTER it.
The 3L field displays the imposed managed speed value.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

MODIFICATION OF THE CABIN RATE

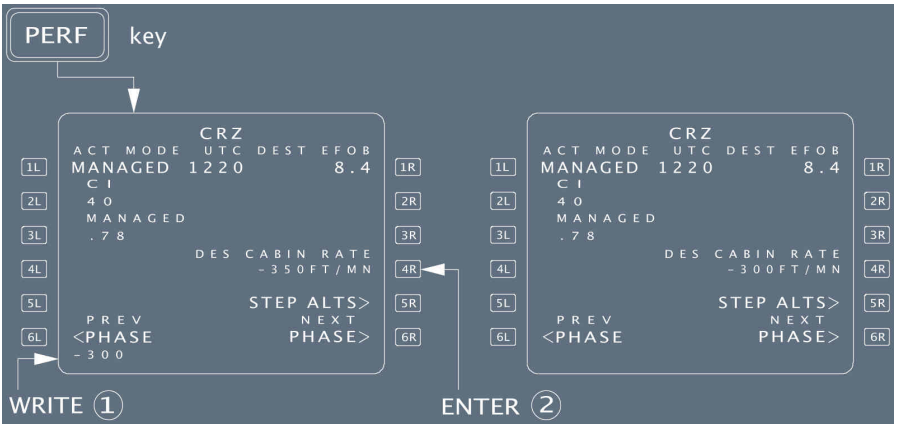


PROCEDURE

PRESS the MCDU's PERF.
WRITE the new cabin rate in the scratchpad.
ENTER it in the [4R] field.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

MODIFICATION OF THE CABIN RATE

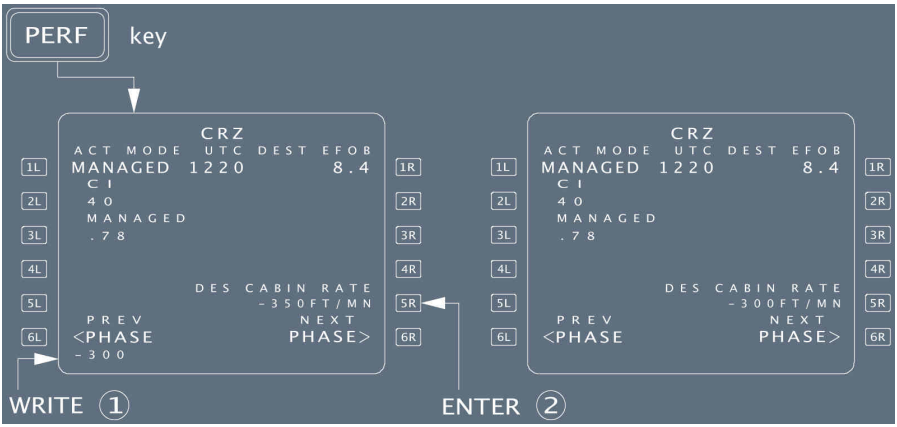


PROCEDURE

PRESS the MCDU's PERF.
WRITE the new cabin rate in the scratchpad.
ENTER it in the [4R] field.

Applicable to: B-HSQ, B-HSR

MODIFICATION OF THE CABIN RATE



PROCEDURE

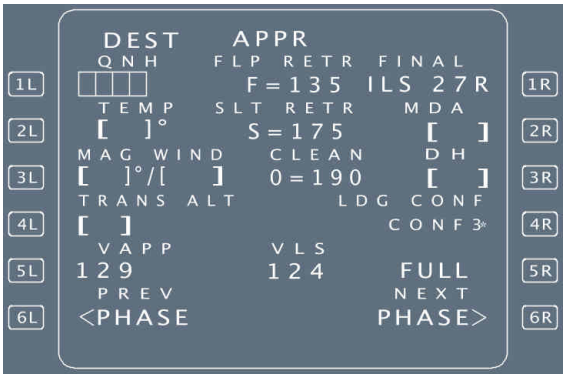
PRESS the MCDU's PERF.
WRITE the new cabin rate in the scratchpad.
ENTER it in the [5R] field.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

ENTERING THE APPROACH DATA

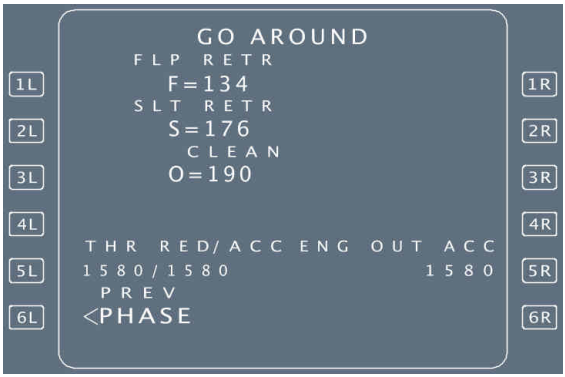
From PERF DES page, SELECT “NEXT PHASE” [6R] key to display the APPR page.
ENTER QNH, TEMP, WIND at destination (magnetic north reference), MDA/MDH or DH.
(The PFD displays the MDA/MDH or DH value, only after the descent phase has been activated.)

CHECK and, if necessary, MODIFY
- LDG CONF (landing configuration)
- VAPP (the FM-computed value may be modified)
- TRANS ALT (transition altitude)



The scratchpad displays "ENTER DEST DATA" if the approach page is not completed when the aircraft is 180 nm from destination.

SELECT "NEXT PHASE" in order to display the GO AROUND page.
CHECK and, if necessary, MODIFY the THR RED ALT and the ACC ALT.



Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

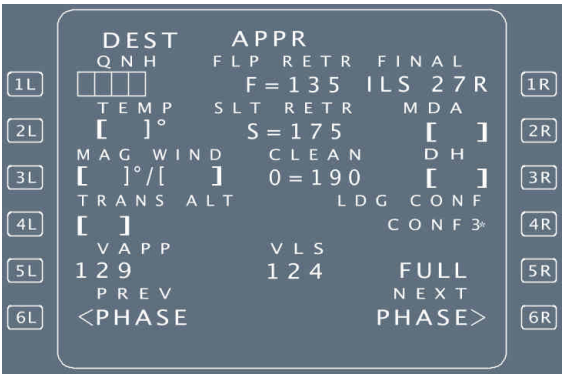
ENTERING THE APPROACH DATA

From PERF DES page, SELECT "NEXT PHASE" [6R] key to display the APPR page.

ENTER QNH, TEMP, WIND at destination (magnetic north reference), DH or MDA (MDH depending on the OPC option).

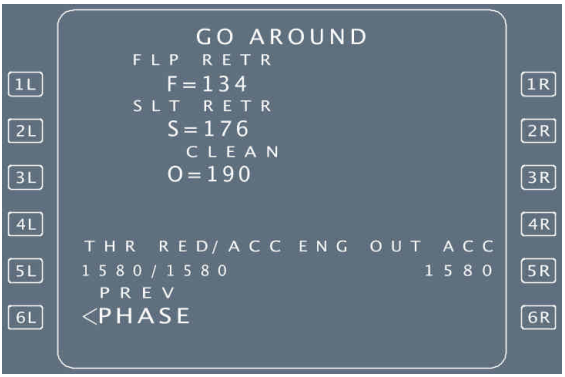
(The PFD displays the MDA/MDH or DH only when the distance to destination is less than 250 nm).

CHECK and, if necessary, MODIFY
- LDG CONF (landing configuration)
- VAPP (the FM-computed value may be modified)
- TRANS ALT (transition altitude)



The scratchpad displays "ENTER DEST DATA" if the approach page is not completed when the aircraft is 180 nm from destination.

SELECT "NEXT PHASE" in order to display the GO AROUND page.
CHECK and, if necessary, MODIFY the THR RED ALT and the ACC ALT.



Applicable to: B-HSQ, B-HSR

ENTERING THE APPROACH DATA

From PERF DES page, SELECT "NEXT PHASE" [6R] key to display the APPR page.
ENTER QNH, TEMP, WIND at destination (magnetic north reference), minimum in the RADIO or BARO fields.

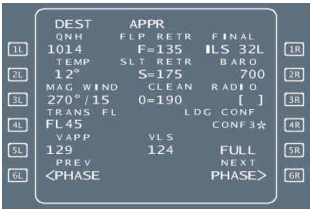
(The PFD displays the entered BARO or RADIO minimum value, only when the distance to destination is less than 250 nm).

CHECK and, if necessary, MODIFY the LDG CONF (landing configuration)
CHECK, and if necessary MODIFY the VAPP

The FMS-computed value may be modified

CHECK the TRANS FL value

(see note 1 below)

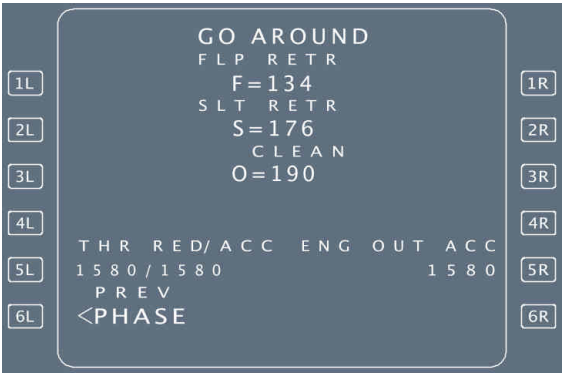


Note: *1. The default TRANS FL value is computed by the FMS based on:*
- *The Transition Altitude of the destination airport (extracted from the NAV Database)*
- *The QNH value entered on PERF APPR page. Due to the internal FMS computation of altitude constraints, it is rounded to the upper multiple of 5.*
  The crew should not modify this default TRANS FL value, if it slightly differs from the Transition Level specified on the approach chart or reported by ATC.

2. The scratchpad displays "ENTER DEST DATA" if the PERF APPR page has not been completed when the aircraft is less than 180 nm from destination.

SELECT "NEXT PHASE" in order to display the GO AROUND page.

CHECK and, if necessary, MODIFY the THR RED ALT and the ACC ALT.



Applicable to: ALL

SELECTING THE RADIO NAVAIDS

CHECK or SELECT the NAVAIDS appropriate for the approach.

For an ILS procedure, the ILS will be autotuned.
NDBs must be manually entered.

Note: When the destination has a VOR/DME, ENTER it manually in the VOR field. ENTER its identifier in the BRG/DIST field of the PROG page. This allows you to perform a permanent NAV accuracy check.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

COST INDEX FOR LONG-RANGE CRUISE

The flight crew can use the table below to find an approximate Cost Index value that is calculated for cruise at long-range cruise speed. This value is valid for CRZ FL = OPT ALT ±10 000 ft.

AIRCRAFT	ENGINE	CILRC	
		kg/min	100 lb/h
A318/A319/A320/A321	CFM 56-5-A4/A5	20	30
	CFM 56-5-A1/A3	45	60
	CFM 56-5-B1/B2/B3	65	85
	CFM 56-5-B4 (A321)	65	85
	CFM 56-5-B4 (A320)	25	35
	CFM 56-5-B4/P	5	10
	CFM 56-5-B5/B6/B7	5	10
	CFM 56-5-B8/B9	15	20
	PW6122/PW6124	20	30
	V2522-A5/V2524-A5/V2527M-A5	30	40
	V2527-A5/V2527E-A5	40	55
	V2500-A1	45	60
	V2530-A5/V2533-A5	50	70

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

COST INDEX FOR LONG-RANGE CRUISE

	V2500-A1	45	60
	V2522-A5/V2524-A5/ V2527M-A5	50	70
	V2530-A5/V2533-A5	50	70
	V2527-A5/V2527E-A5	40	55

Intentionally left blank

Descent

DESCENT INITIATION

Applicable to: ALL

The top of descent, displayed on the F-PLN page (T/D) and on the ND ( ), is a position that the system calculates, assuming that the aircraft will begin its descent in DES mode with managed speed, and that the system will guide the aircraft along the descent profile computed with all the vertical F-PLN data (ALT CSTR, ECON or AUTO MACH/SPD, SPD CSTR, SPD LIMIT) to reach VAPP at 1 000 ft AGL.

Note: The ND does not display the top of descent when HDG (or TRACK) mode is engaged.

PROCEDURES

- **When the aircraft reaches the top of descent (F/D) :**

  SELECT the altitude target.

  PUSH the ALT selector knob. DES mode engages.

  CHECK the FMA annunciators.

DESCENT MONITORING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

DES MODE ENGAGED

When DES mode is engaged, NAV mode is engaged, and the system takes into account all altitude and speed constraints.
The key parameter for monitoring the descent is the vertical deviation (VDEV) displayed on the PFD and on the PROG page, which indicates whether the aircraft is on, above, or below the descent profile.

PROCEDURE

SET the ATC-cleared altitude on the FCU (considering also what is the safe altitude).

If the lowest safe altitude is higher than the ATC-cleared altitude, check with ATC that this constraint applies.
If it is confirmed, SET the FCU altitude to the safe altitude until it is safe to go to the ATC-cleared altitude.

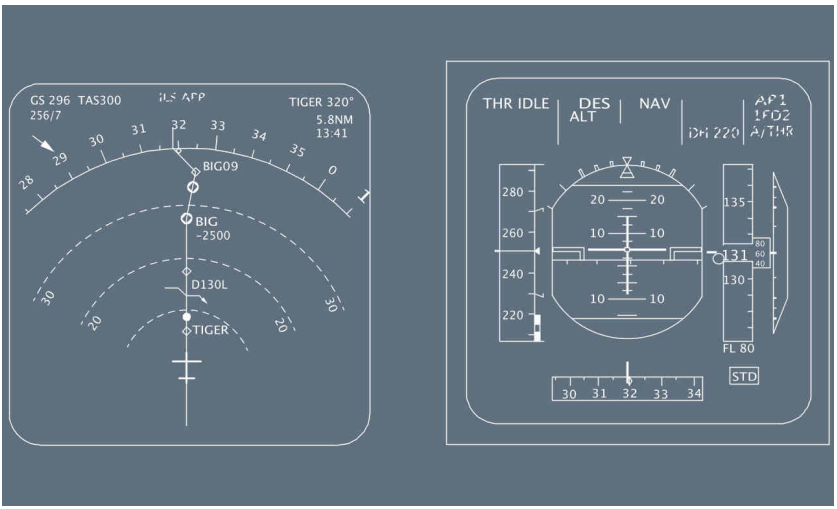
MONITOR vertical deviation (VDEV) on the PFD and the PROG page.
MONITOR the speed change that occurs, when the aircraft reaches a speed change symbol (magenta ball) under managed speed.
MONITOR the FMA (ALT*, ALT CST*, ALT, ALT CST), when the aircraft reaches level symbols.

■ **If the aircraft is on the descent profile:**

The aircraft is considered to be on the vertical profile, when it is within 50 ft of it. VDEV is close to zero, and the system predicts that it will match constraints until the aircraft levels off at the next FCU altitude.

MONITOR the predicted descent point after the next level-off.

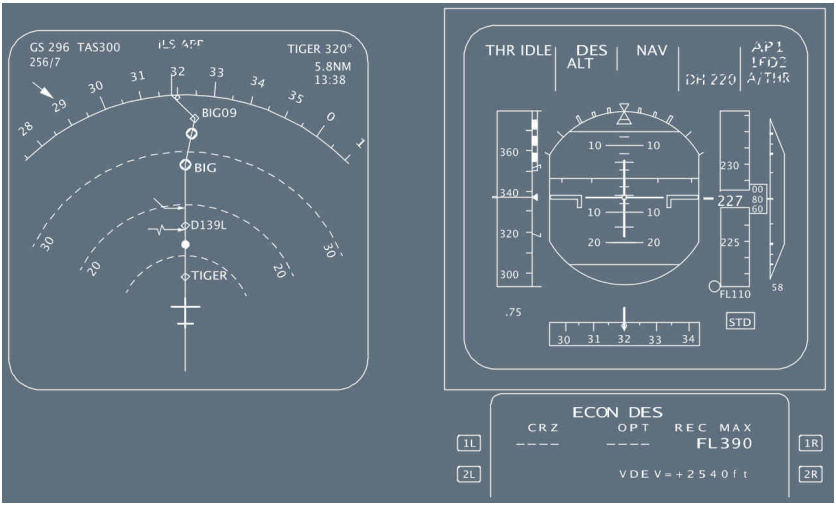
The A/THR adjusts the thrust for the particular segment. The first FMA column may display "THR IDLE" or "SPEED".



■ **If the aircraft is above the descent profile:**

VDEV is down on the PFD and positive on the PROG page.

The A/THR sets IDLE thrust and the AP increases speed by calling for down elevator. If the aircraft reaches the upper limit of the managed speed range, the aircraft diverges and maintains the upper limit speed.



Procedure

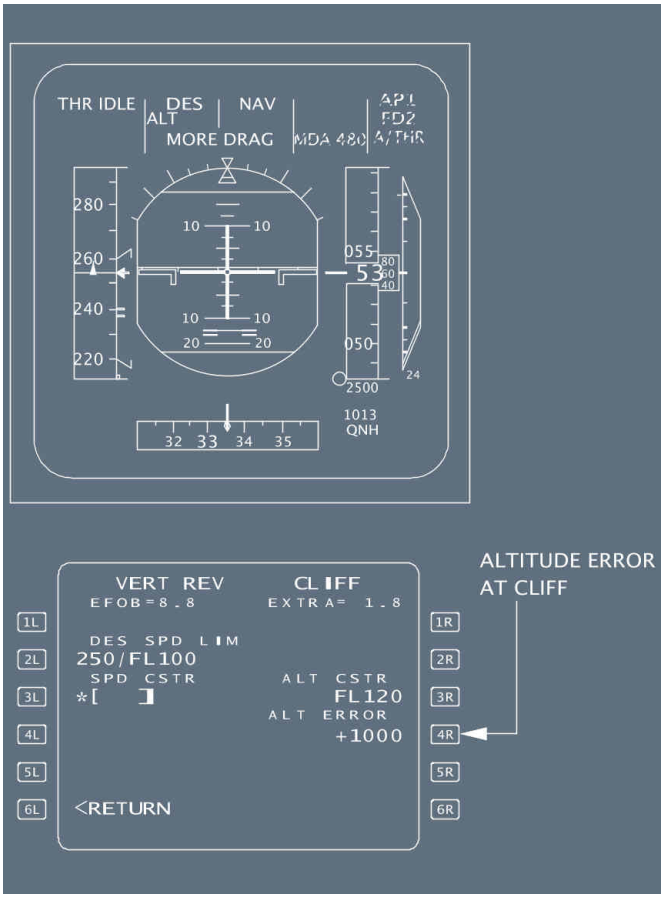
SELECT a descent speed higher than the upper limit when possible.

MONITOR the intercept symbol.

When this symbol reaches the next ALT CSTR waypoint, "MORE DRAG" appears on the PFD, indicating that speedbrakes must be extended in order to match the next altitude constraint. This is an advisory message.

Note: *When DES mode is engaged, speed brake extension will not necessarily increase the descent rate. It does so, if the aircraft is above the profile.*
If the aircraft is on or below the profile: The system will add thrust to keep the aircraft on profile and within the speed target range.

- **If an <u>altitude constraint</u> is predicted to be missed by more than 250 ft,** the vertical revision page shows ALT ERROR at the waypoint.

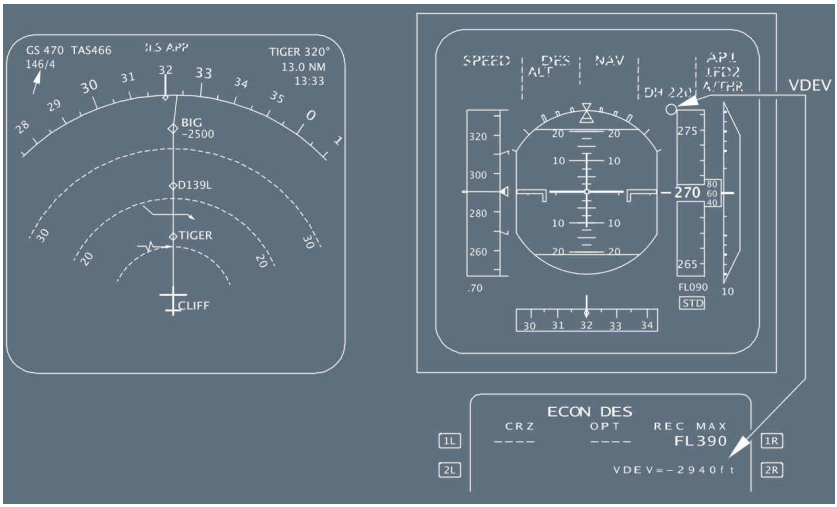


- **If a <u>speed constraint</u> is predicted to be missed by more than 10 kt:**
  SELECT an appropriate speed.
  RESUME managed speed when the aircraft is back on the descent path.

■ **If the aircraft is below the descent profile:**
VDEV is up on the PFD and negative on the PROG page. The system maintains the target speed (managed or selected speed).

MONITOR the intercept symbol ([]) on the ND and any leveling off at the next ALT CSTR.

The A/THR is in speed mode with a -1 000 ft/min rate of descent (if the aircraft is flying an idle segment) or half the theoretical FPA of the descent profile (if the aircraft is flying a geometric segment), until the profile is regained.



- **If the rate of descent has to be increased (ATC requirement):**

  SELECT OP DES mode

  Increase the target speed or extend the speedbrakes.

Applicable to: B-HSJ, B-HSK, B-HTG, B-HTH, B-HTI

DES MODE ENGAGED

When DES mode is engaged, NAV mode is engaged, and the system takes into account all altitude and speed constraints.

The key parameter for monitoring the descent is the vertical deviation (VDEV) displayed on the PFD and on the PROG page, which indicates whether the aircraft is on, above, or below the descent profile.

PROCEDURE

SET the ATC-cleared altitude on the FCU (considering also what is the safe altitude).

If the lowest safe altitude is higher than the ATC-cleared altitude, check with ATC that this constraint applies.

If it is confirmed, SET the FCU altitude to the safe altitude until it is safe to go to the ATC-cleared altitude.

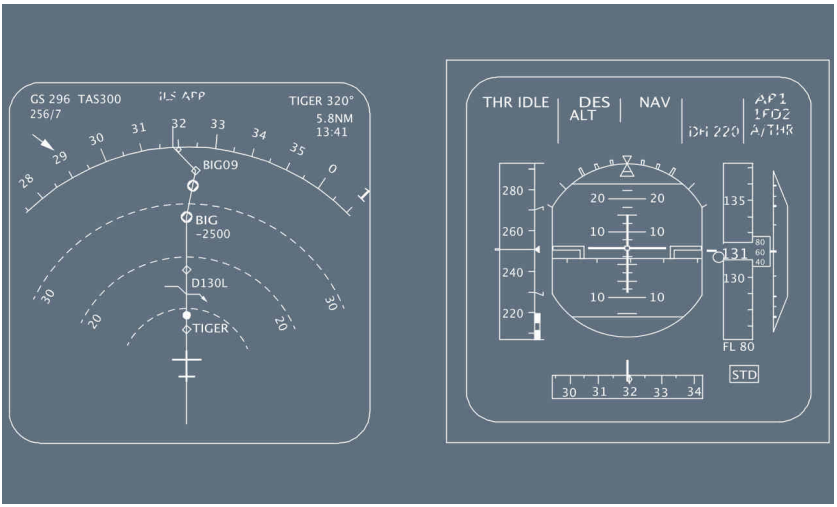
MONITOR the vertical deviation (VDEV) on the PFD and the PROG page.
MONITOR the speed change that occurs, when the aircraft reaches a speed change symbol (magenta ball) under managed speed.
MONITOR the FMA (ALT*, ALT CST*, ALT, ALT CST) when the aircraft reaches level symbols.

■ **If the aircraft is on the descent profile:**

The aircraft is considered to be on the vertical profile, when it is within 50 ft of it. VDEV is close to zero, and the system predicts that it will match constraints until the aircraft levels off at the next FCU altitude.

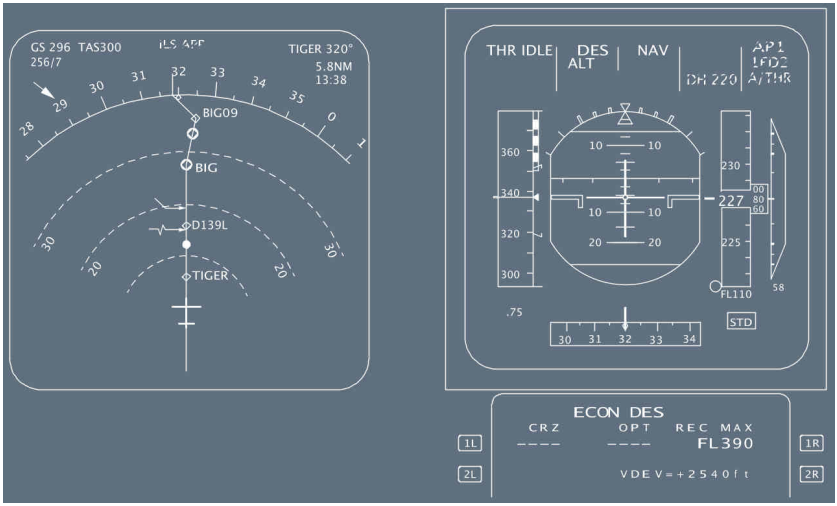
MONITOR the predicted descent point after the next level-off.

The A/THR adjusts the thrust for the particular segment. The first FMA column may display "THR IDLE" or "SPEED".



■ **If the aircraft is above the descent profile:**

VDEV is down on the PFD and positive on the PROG page.
The A/THR sets IDLE thrust and the AP increases speed by calling for down elevator. If the aircraft reaches the upper limit of the managed speed range, the aircraft diverges and maintains the upper limit speed.



Procedure

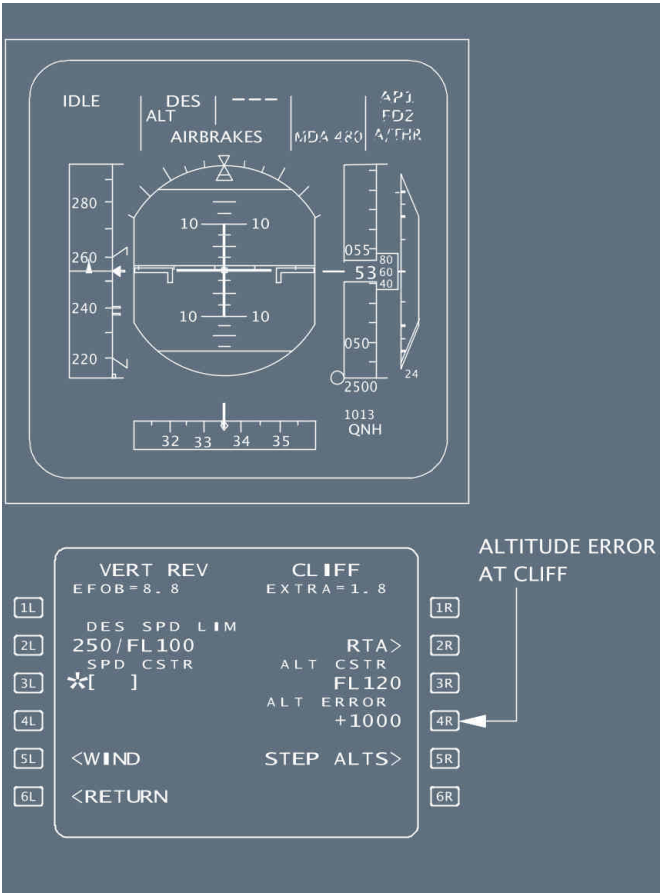
SELECT a descent speed higher than the upper limit when possible.

MONITOR the intercept symbol.

When this symbol reaches the next ALT CSTR waypoint "MORE DRAG" appears on the PFD indicating that speedbrakes must be extended in order to match the next altitude constraint. This is an advisory message.

Note: *When DES mode is engaged, the speed brake extension will not necessarily increase the descent rate. It does so only, if the aircraft is above the profile. If the aircraft is on or below the profile: The system will add thrust to keep the aircraft on profile and within the speed target range.*

- **If an <u>altitude constraint</u> is predicted to be missed by more than 250 ft,** the vertical revision page shows ALT ERROR at the waypoint.



- **If a <u>speed constraint</u> is predicted to be missed by more than 10 kt:**
  SELECT an appropriate speed.
  RESUME managed speed when the aircraft is back on the descent path.

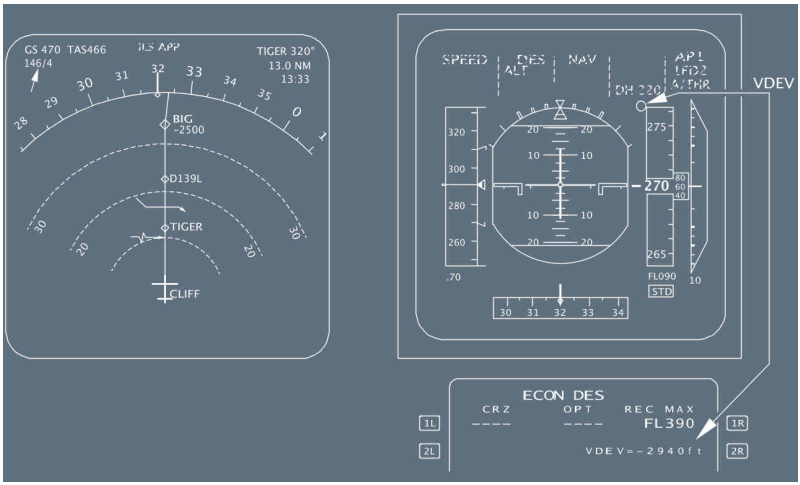
■ **If the aircraft is below the descent profile:**
VDEV is up on the PFD and negative on the PROG page. The system maintains the target speed (managed or selected speed).

MONITOR the intercept symbol ([ ]) on the ND and any leveling off at the next ALT CSTR.

- **If the aircraft is flying at an altitude that is higher than both the descent speed limit altitude and the destination elevation +5 000 ft:**

  The FMGS maintains the V/S at -1 000 ft/min and the target speed, until the aircraft reaches the altitude constraint or intercepts the descent profile.

- **If the aircraft is flying at an altitude that is lower than either the descent speed limit altitude, or the destination elevation +5 000 ft:**
  The FMGS maintains the V/S at - 500 ft/min and the target speed, until the aircraft reaches the altitude constraint or intercepts the descent profile.



- **If the rate of descent has to be increased (ATC requirement):**
  SELECT OP DES mode
  Increase the target speed or extend the speedbrakes.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

DES MODE ENGAGED

When DES mode is engaged, NAV mode is engaged, and the system takes into account all altitude and speed constraints.
The key parameter for monitoring the descent is the vertical deviation (VDEV) displayed on the PFD and on the PROG page, which indicates whether the aircraft is on, above, or below the descent profile.

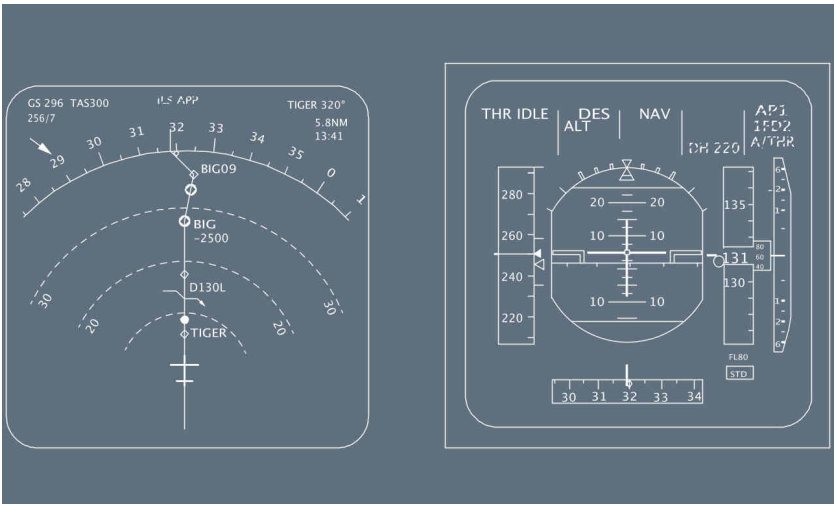
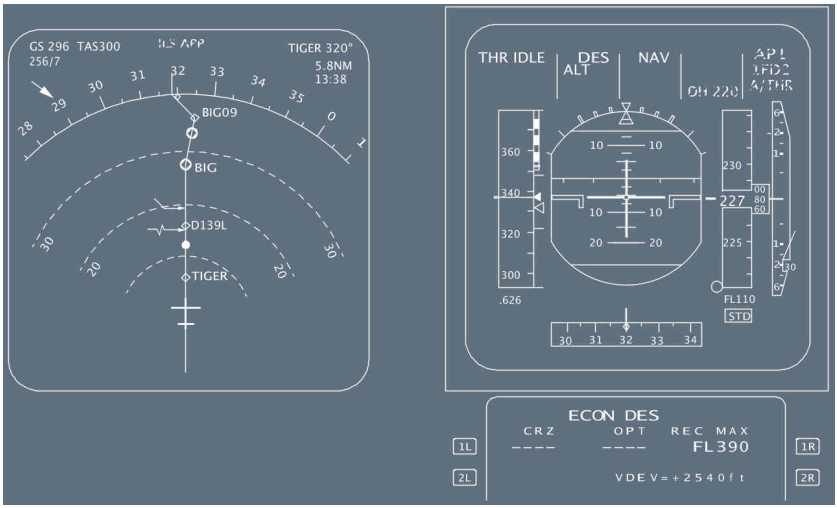
A/THR adjusts thrust for the particular segment. The first FMA column may display "THR IDLE" or "SPEED".



■ **If the aircraft is above the descent profile:**
VDEV is down on the PFD and positive on the PROG page.

A/THR sets IDLE thrust and the AP increases speed by calling for down elevator. If the aircraft reaches the upper limit of the managed speed range, the aircraft diverges and maintains the upper limit speed.



Procedure

SELECT a descent speed higher than the upper limit when possible.

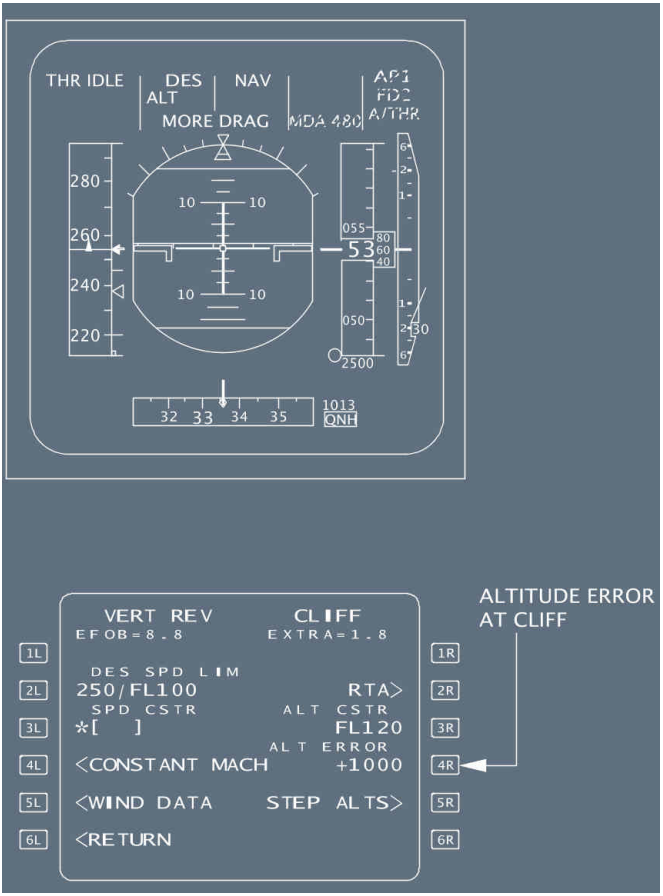
MONITOR the intercept symbol.

When this symbol reaches the next ALT CSTR waypoint, "MORE DRAG" appears on the PFD, indicating that speedbrakes must be extended in order to match the next altitude constraint. This is an advisory message.

Note: When DES mode is engaged, speed brake extension will not necessarily increase the descent rate. It does so, if the aircraft is above the profile.
If the aircraft is on or below the profile: The system will add thrust to keep the aircraft on profile and within the speed target range.

- **If an <u>altitude constraint</u> is predicted to be missed by more than 250 ft** the vertical revision page shows ALT ERROR at the waypoint.



- **If a <u>speed constraint</u> is predicted to be missed by more than 10 kt:**

  SELECT an appropriate speed.

  RESUME managed speed when the aircraft is back on the descent profile.

■ **If the aircraft is below the descent profile**

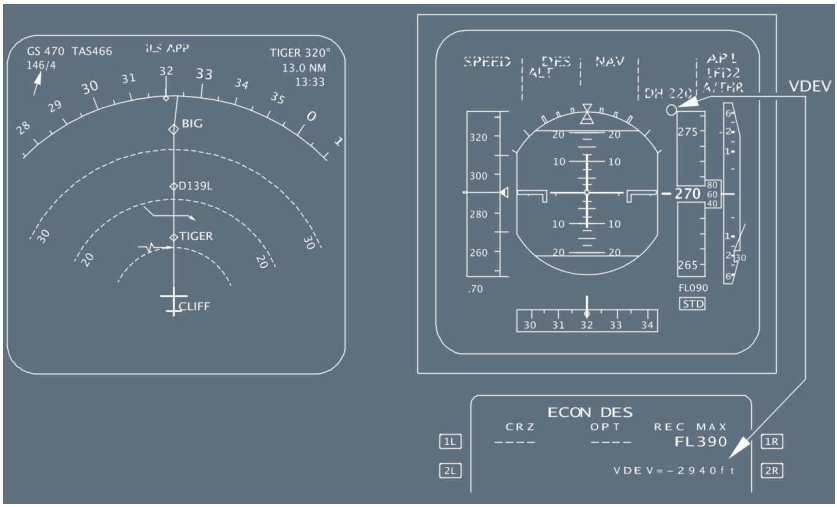
VDEV is up on the PFD and negative on the PROG page. The system maintains the target speed (managed or selected speed).

MONITOR the intercept symbol ([ ]) on the ND and any leveling off at the next ALT CSTR.

- **If the aircraft is flying at an altitude that is higher than both the descent speed limit altitude and the destination elevation +5 000 ft:**

  The FMGS maintains the V/S at -1 000 ft/min and the target speed, until the aircraft reaches the altitude constraint or intercepts the descent profile.

■ **If the aircraft is flying at an altitude that is lower than either the descent speed limit altitude, or the destination elevation +5 000 ft:**
The FMGS maintains the V/S at - 500 ft/min and the target speed, until the aircraft intercepts either the altitude constraint or the descent profile.

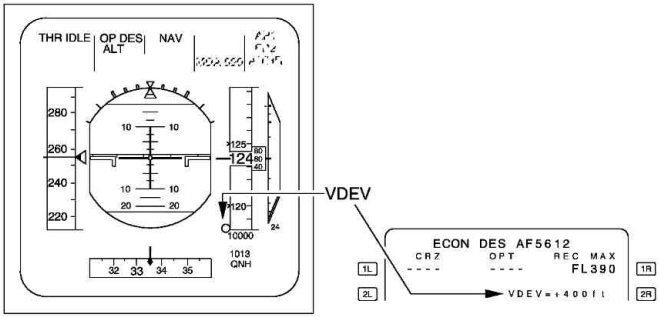


- **<u>If the rate of descent has to be increased (ATC requirement):</u>**
  SELECT OP DES mode
  Increase the target speed or extend the speedbrakes.

Applicable to: B-HSD, B-HSE

OP DES, V/S OR FPA MODE ENGAGED

- In either case, the aircraft is no longer guided on the descent profile and altitude constraints are disregarded. If NAV mode is engaged the ND displays a white circle on waypoint with an altitude constraint. If NAV mode is disengaged, the circle is removed.
- The PFD still shows VDEV for reference purposes.
- The target altitude is always the FCU selected altitude (shown in blue).
  On the ND, level-off symbol is blue (no constraint). If NAV mode is engaged and the speed target managed, speed constraints are considered.



Vertical position may also be assessed by comparing the required distance to land and the distance to destination. The required distance to land is the distance to descend from the present level down to VAPP at destination elevation, taking into account current speed, speed limit (if any) wind compensation and an approach segment at VAPP.

Depending on aircraft configuration, the required distance to land is displayed :

- On the MCDU progress page, when HDG or TRK mode is engaged.

- On the ND by the energy circle, when HDG or TRK mode is engaged. It is displayed as a green arc oriented on the current track and centered on the aircraft current position.

Note: Altitude and speed predictions displayed on the F-PLN page assume an immediate return to DES mode.

PROCEDURE

SET the FCU altitude as cleared by ATC, while considering the applicable safe altitude.

If the next safe altitude is higher than the ATC-cleared altitude, check with the ATC to verify that this constraint applies.
If confirmed, set the FCU altitude to the safe altitude, until it is safe to fly at the cleared altitude.

MONITOR the speed target, when the aircraft reaches the speed change symbol.
MONITOR the FMA ALT*, ALT, upon reaching the level symbol.
When in HDG/TRK mode, MONITOR the energy circle on the ND.

The MCDU F-PLN page presents SPD/ALT constraint-matching predictions, which assume that DES mode is immediately re-engaged.

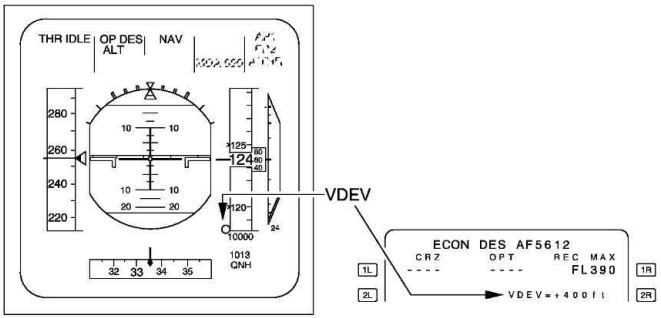
CHECK the predictions before re-engaging DES mode (in order to resume the descent profile).

Note: VDEV is available on the PFD even in HDG mode; it is a valuable tool for monitoring the descent, as long as crosstrack error (XTK) is less than 5 nm.
The aircraft automatically decelerates for approach, only if it flies over the DECEL pseudo waypoint with NAV mode engaged (or LOC, LOC).*

Applicable to: B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

OP DES, V/S OR FPA MODE ENGAGED

- In either case, the aircraft is no longer guided on the descent profile and altitude constraints are disregarded. If NAV mode is engaged the ND displays a white circle on waypoint with an altitude constraint. If NAV mode is disengaged, the circle is removed.
- The PFD still shows VDEV for reference purposes.
- The target altitude is always the FCU selected altitude (shown in blue).
  On the ND, level-off symbol is blue (no constraint). If NAV mode is engaged and the speed target managed, speed constraints are considered.



When HDG or TRK mode is engaged, vertical position may also be assessed on the ND using the energy circle. It is displayed as a green arc oriented on the current track and centered on the aircraft current position.

Note: *Altitude and speed predictions displayed on the F-PLN page assume an immediate return to DES mode.*

PROCEDURE

SET the FCU altitude as cleared by ATC, while considering the applicable safe altitude.

If the next safe altitude is higher than the ATC-cleared altitude, check with the ATC to verify that this constraint applies.
If confirmed, set the FCU altitude to the safe altitude, until it is safe to fly at the cleared altitude.

MONITOR the speed target, when the aircraft reaches the speed change symbol.
MONITOR the FMA ALT*, ALT, upon reaching the level symbol.
When in HDG/TRK mode, MONITOR the energy circle on the ND.

The MCDU F-PLN page presents SPD/ALT constraint-matching predictions, which assume that DES mode is immediately re-engaged.

CHECK the predictions before re-engaging DES mode (in order to resume the descent profile).

Note: *VDEV is available on the PFD even in HDG mode; it is a valuable tool for monitoring the descent, as long as crosstrack error (XTK) is less than 5 nm.*
The aircraft automatically decelerates for approach, only if it flies over the DECEL pseudo waypoint with NAV mode engaged (or LOC, LOC).*

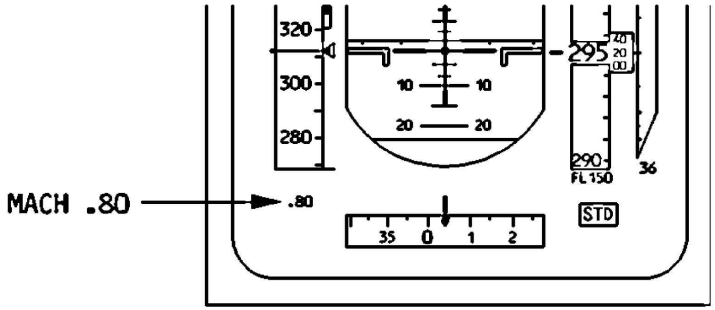
EXPEDITE DESCENT (IF INSTALLED)

Applicable to: ALL

- **When ATC requires a rapid descent :**

  DEPRESS THE EXPED pushbutton

  Flight guidance (FG) pitches the aircraft to acquire and maintain 0.80/340. FG orders a pitch rate that produces no more than 0.15 g. The pilot can use this mode to initiate an emergency descent. To resume normal descent, PUSH the ALT selection knob or engage any other vertical mode.



MONITORING THE NAVIGATION IN THE TERMINAL CONTROL AREA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

If the MCDU "SYSTEM RNP IS XX.X" message is displayed, the pilot will verify the manually-entered RNP value in the REQUIRED field of the PROG page and clear or modify it, if it is not in accordance with the RNP value specified in the area (NAV or approach chart).

MONITORING THE NAVIGATION IN THE TERMINAL CONTROL AREA

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

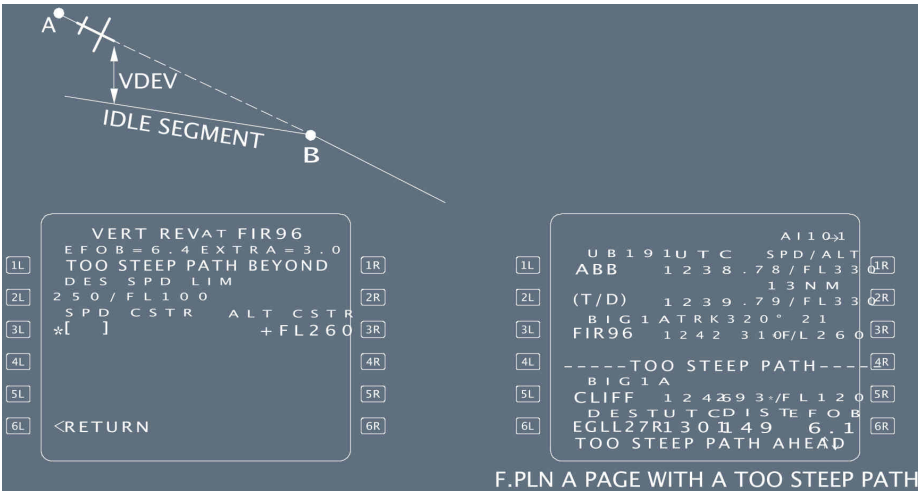
If the MCDU "AREA RNP IS XX.X" message or "PROCEDURE RNP IS XX.X" message is displayed, the pilot will manually-entered RNP value in the REQUIRED field of the PROG page and clear or modify it, if it is not in accordance with the RNP value specified in the area (NAV or approach chart).

TOO STEEP PATH

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

"TOO STEEP PATH AHEAD" appears on the MCDU scratchpad, when the system predicts this situation, and TOO STEEP PATH is displayed on the F-PLN page.

When the aircraft is crossing the first waypoint of a TOO STEEP PATH, the system computes a flyable descent profile (with an idle segment). The VDEV makes a jump because it is related to a new profile.



PROCEDURE

- **When passing the first waypoint of the TOO STEEP PATH:**

  MONITOR VDEV and predictions at the next CSTR waypoint.

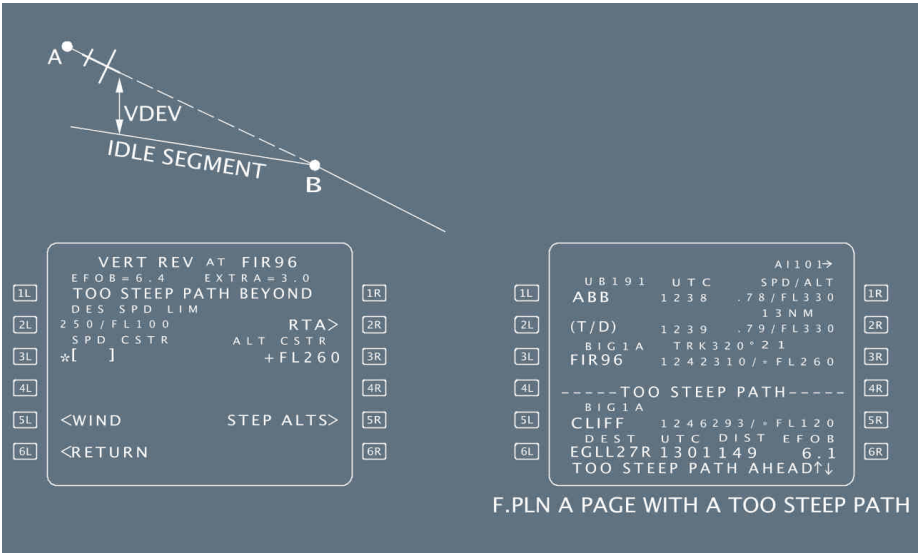
  If required, EXTEND the speedbrakes before seeing the “MORE DRAG” (or “AIRBRAKES”) message.

  CONSIDER using a holding pattern, if necessary.

TOO STEEP PATH

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

“TOO STEEP PATH AHEAD” appears on the MCDU scratchpad, when the system predicts this situation, and TOO STEEP PATH is displayed on the F-PLN page.
When the aircraft is crossing the first waypoint of a TOO STEEP PATH, the system computes a flyable descent profile (with an idle segment). The VDEV makes a jump because it is related to a new profile.



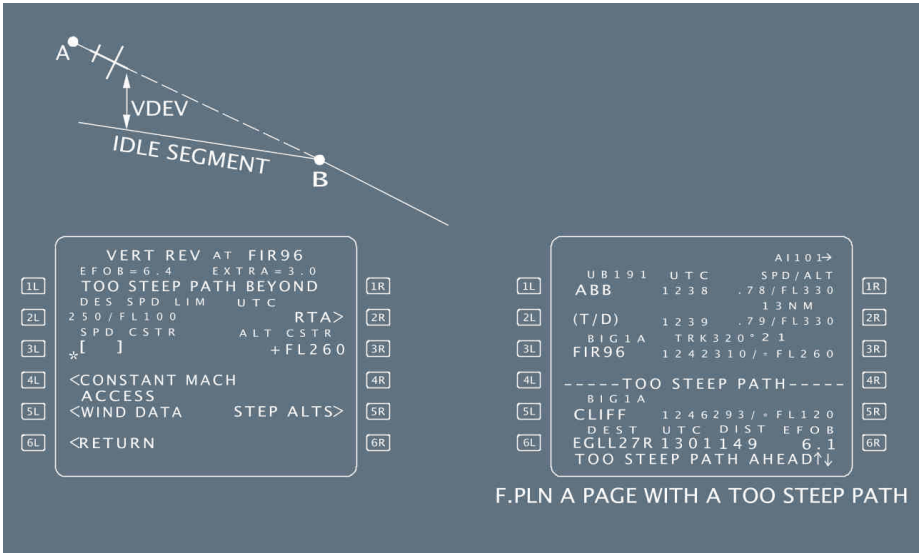
PROCEDURE

- **When passing the first waypoint of the TOO STEEP PATH:**
  MONITOR VDEV and predictions at the next CSTR waypoint.
  If required, EXTEND the speedbrakes before seeing the “MORE DRAG” message.
  CONSIDER using a holding pattern, if necessary.

TOO STEEP PATH

Applicable to: B-HSQ, B-HSR

“TOO STEEP PATH AHEAD” appears on the MCDU scratchpad, when the system predicts this situation, and TOO STEEP PATH is displayed on the F-PLN page.
When the aircraft is crossing the first waypoint of a TOO STEEP PATH, the system computes a flyable descent profile (with an idle segment). The VDEV makes a jump because it is related to a new profile.



F.PLN A PAGE WITH A TOO STEEP PATH

PROCEDURE

- **When passing the first waypoint of the TOO STEEP PATH:**
  MONITOR VDEV and predictions at the next CSTR waypoint.
  If required, EXTEND the speedbrakes before seeing the “MORE DRAG” message.
  CONSIDER using a holding pattern, if necessary.

HOLDING PATTERN

Applicable to: ALL

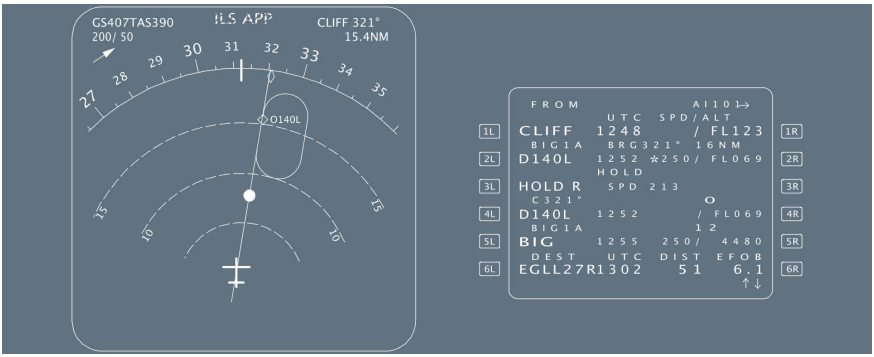
A hold may be required during the descent, and may be manually inserted.

PROCEDURE

PRESS the F-PLN key.
SELECT the lateral revision page.
SELECT the HOLD prompt.
CHECK the HOLDING data, and MODIFY it if necessary.

CHECK the temporary flight plan and INSERT the holding pattern in it.

Note: If the holding fix is close to the DECEL pseudo waypoint and the speed is managed, manually activate the approach phase to change the managed target speed to approach speed (VAPP). This will avoid having an increase of speed not appropriate.



MANUAL TERMINATION

Applicable to: ALL

You should not use DES mode when entering a leg with manual termination. Manual termination, which is defined as a track or a heading with no termination, is always part of a database procedure. The computed descent flight profile may not be adequate when flying this type of leg.

Intentionally left blank

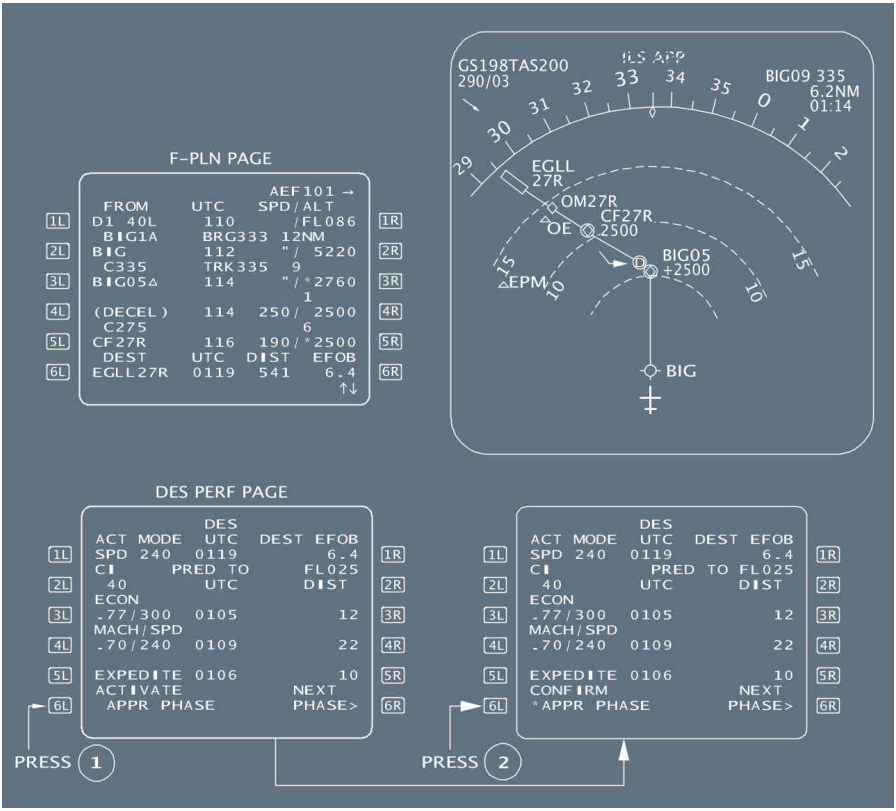
Approach

INITIAL APPROACH

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

UPON REACHING THE INITIAL APPROACH AREA

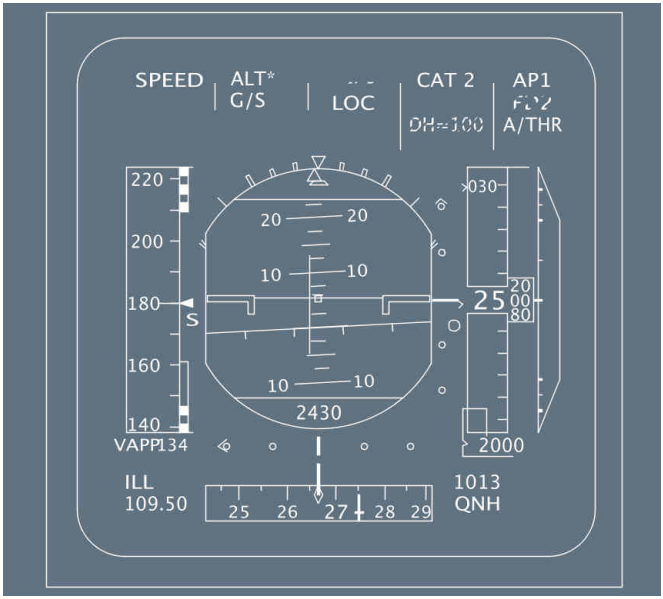
- Approach phase will activate automatically when flying over the DECEL pseudo waypoint with NAV, APPR NAV or LOC* or LOC mode engaged.
- You will activate manually the approach phase on the PERF page if:
  - HDG or TRK mode is engaged, or
  - You are flying a go around, or
  - An early deceleration is required



MANAGED SPEED

CHECK that managed speed is active: MONITOR the target speed.

During the approach, the autothrust limits the speed of the current configuration. (GD, S, F, VAPP).



- **If ATC requires a specific speed:**
  SWITCH to selected speed (turn and pull the speed selector knob on the FCU).
  ADJUST the aircraft configuration accordingly.
- **If ATC orders successive step descents down to the final approach flight path:**
  Use the V/S or FPA mode.
  MONITOR VDEV.

NAV ACCURACY

As required by the SOP.
Without installed GPS and when no DME is available for the accuracy check, use HIGH/LOW on the PROG page.
In this case, consider a "HIGH" to be equivalent to a positive crosscheck.

ATC CLEARANCE

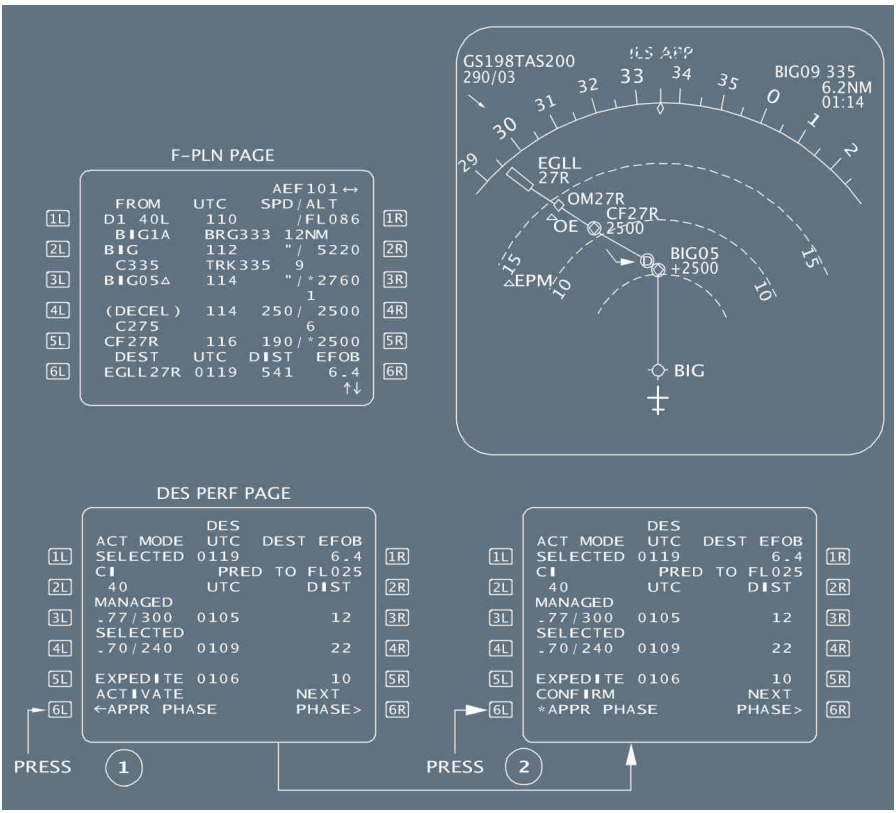
MODIFY the F-PLN, RAD NAV, and PERF APPR data to agree with the latest clearance and landing information.

INITIAL APPROACH

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

UPON REACHING THE INITIAL APPROACH AREA

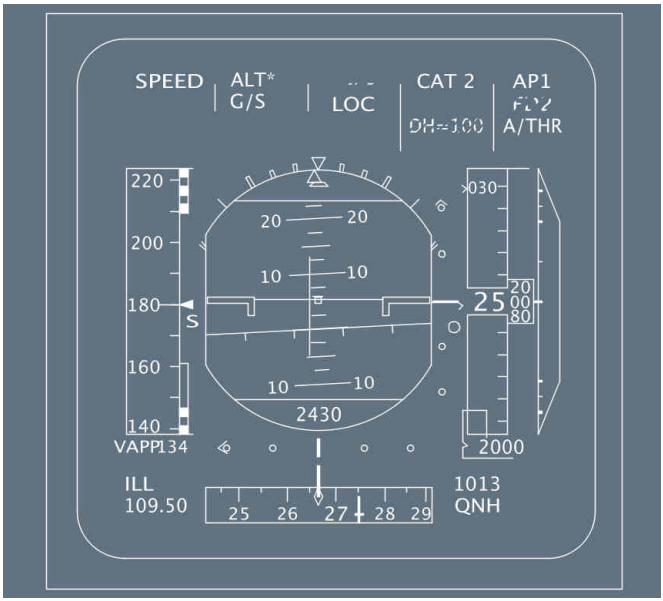
- Approach phase will activate automatically when flying over the DECEL pseudo waypoint with NAV, APPR NAV or LOC* or LOC mode engaged.
- You will activate manually the approach phase on the PERF page if:
  - HDG or TRK mode is engaged, or
  - You are flying a go around, or
  - An early deceleration is required



MANAGED SPEED

CHECK that managed speed is active: MONITOR the target speed.

During the approach, the autothrust limits the speed of the current configuration. (GD, S, F, VAPP).



- **If ATC requires a specific speed:**

  SWITCH to selected speed (turn and pull the speed selector knob on the FCU).

  ADJUST the aircraft configuration accordingly.

- **If ATC orders successive step descents down to the final approach flight path:**

  Use the V/S or FPA mode.

  MONITOR VDEV.

NAV ACCURACY

As required by the SOP.

Without installed GPS and when no DME is available for the accuracy check, use HIGH/LOW on the PROG page.

In this case, consider a “HIGH” to be equivalent to a positive crosscheck.

ATC CLEARANCE

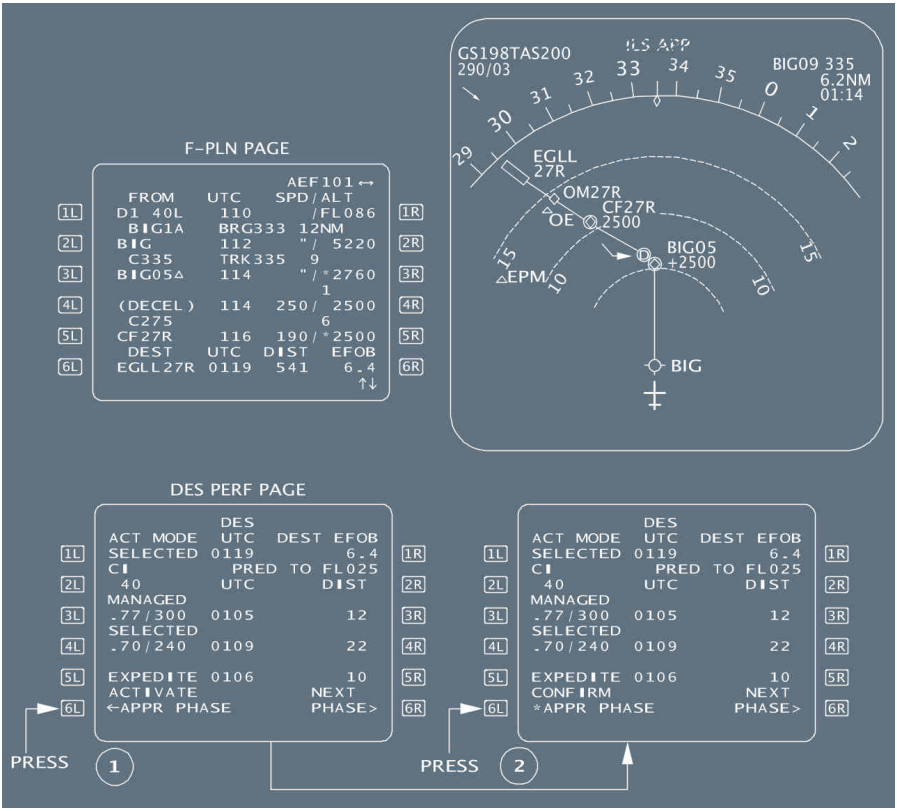
MODIFY the F-PLN, RAD NAV, and PERF APPR data to agree with the latest clearance and landing information.

INITIAL APPROACH

Applicable to: B-HSQ, B-HSR

UPON REACHING THE INITIAL APPROACH AREA

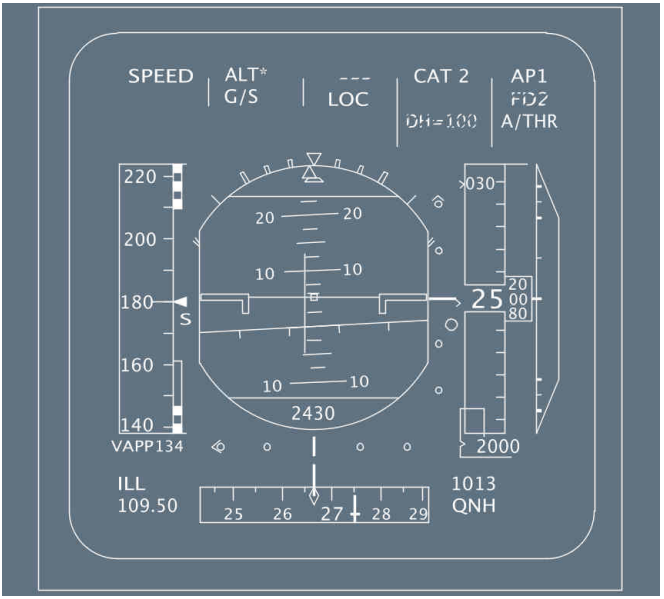
- Approach phase will activate automatically when flying over the DECEL pseudo waypoint with NAV, LOC*, LOC, F-LOC* or F-LOC mode engaged.
- You will activate manually the approach phase on the PERF page if:
  - HDG or TRK mode is engaged, or
  - You are flying a go around, or
  - An early deceleration is required



MANAGED SPEED

CHECK that managed speed is active: MONITOR the target speed.

During the approach, the autothrust limits the speed of the current configuration. (GD, S, F, VAPP).



- **If ATC requires a specific speed:**
  SWITCH to selected speed (turn and pull the speed selector knob on the FCU).
  ADJUST the aircraft configuration accordingly.

- **If ATC orders successive step descents down to the final approach flight path:**
  Use the V/S or FPA mode.
  MONITOR VDEV.

NAV ACCURACY

As required by the SOP.
For Non Precision Approaches flown with the FLS function, the flight crew must check the FLS capability.
Without installed GPS and when no DME is available for the accuracy check, use HIGH/LOW on the PROG page.
In this case, consider a "HIGH" to be equivalent to a positive crosscheck.

ATC CLEARANCE

MODIFY the F-PLN, RAD NAV, and PERF APPR data to agree with the latest clearance and landing information.

ILS/MLS/GLS/FLS APPROACH

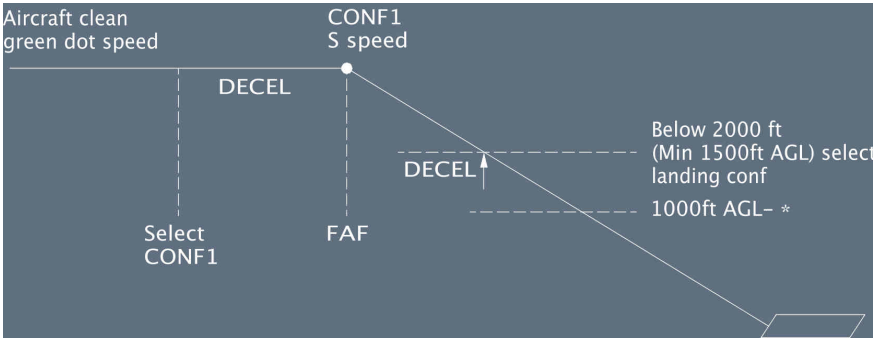
Applicable to: ALL

INTERMEDIATE/FINAL APPROACH (ILS APPROACH ENTERED IN THE F-PLN)

The preferred technique for flying an ILS approach is to fly a decelerated approach using the AP/FDs, the LOC and G/S modes, A/THR in the SPEED mode, managed speed target is recommended.

DECELERATED APPROACH

The decelerated approach technique brings the aircraft down to 1 000 ft, at VAPP. In most cases, the interception of the final descent path is achieved with CONF 1 at S speed.



(*) The approach must be stabilized at approach speed (minimum ground speed) in the landing configuration before reaching 1 000 ft AGL.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

APPROACH MODE ACTIVATION (LOC-G/S)

- **When cleared by ATC and when appropriate:**

  DEPRESS the APPR pushbutton to arm the APPR mode for the approach entered in the flight plan.

  Note: If a NON PRECISION approach is selected in the active flight plan and if the flight crew manually tunes an ILS on the RAD NAV page, the MCDU displays "CHECK APPR GUIDANCE" and the PFD displays "CHECK APP GUIDANCE" or "CHECK APP SEL" (if CPIP3 installed). These messages are a reminder to the flight crew that, although an ILS is tuned on RAD NAV page, the available approach guidance modes are APP NAV-FINAL when the APPR pushbutton is pressed in on the FCU.

The FCU APPR pushbutton arms or engages LOC and G/S modes, if:
- An ILS approach is entered in the flight plan, or
- No approach, or only a runway, is entered in the flight plan, and an ILS is manually-tuned on the RAD NAV page, or
- Both RMPs are set to NAV, and an ILS is selected.

Applicable to: B-HSJ, B-HSK, B-HTG, B-HTH, B-HTI

APPROACH MODE ACTIVATION (LOC-G/S)

● **When cleared by ATC and when appropriate:**

DEPRESS the APPR pushbutton to arm the APPR mode for the approach entered in the flight plan.

Note: *If a NON PRECISION approach is selected in the active flight plan and if the flight crew manually tunes an ILS on the RAD NAV page, the MCDU displays "CHECK APPR SELECTION" and the PFD displays "CHECK APP GUIDANCE" or "CHECK APP SEL" (if CPIP3 installed). These messages are a reminder to the flight crew that, although an ILS is tuned on RAD NAV page, the available approach guidance modes are APP NAV-FINAL when the APPR pushbutton is pressed in on the FCU.*

The FCU APPR pushbutton arms or engages LOC and G/S modes, if:
- An ILS approach is entered in the flight plan, or
- No approach, or only a runway, is entered in the flight plan, and an ILS is manually-tuned on the RAD NAV page, or
- Both RMPs are set to NAV, and an ILS is selected.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

APPROACH MODE ACTIVATION (LOC-G/S)

● **When cleared by ATC and when appropriate:**

DEPRESS the APPR pushbutton to arm the APPR mode for the approach entered in the flight plan.

Note: *If a NON PRECISION approach is selected in the active flight plan and if the flight crew manually tunes an ILS on the RAD NAV page, the MCDU and the PFD display "CHECK APPR SELECTION". This message is a reminder to the flight crew that, although an ILS is tuned on RAD NAV page, the available approach guidance modes are APP NAV-FINAL when the APPR pushbutton is pressed in on the FCU.*

The FCU APPR pushbutton arms or engages LOC and G/S modes, if:
- An ILS approach is entered in the flight plan, or
- No approach, or only a runway, is entered in the flight plan, and an ILS is manually-tuned on the RAD NAV page, or
- Both RMPs are set to NAV, and an ILS is selected.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

AUTOLAND

CHECK that the FMA displays the aircraft capability (CAT 2 or CAT 3) for the intended ILS approach.
MONITOR the radio automatic callout.

- **At 350 ft RA:**

  CHECK that "LAND" is displayed on the FMA.

  CHECK ILS course.

  If LAND is not displayed or if the ILS course is not correct, do not perform an autoland. The flight crew should perform a go-around, if visual references are not sufficient.

- **Between 50 and 40 ft RA:**

  CHECK that "FLARE" is displayed on the FMA.

- **At approximately 30 ft RA:**

  CHECK that "IDLE" is displayed on the FMA, and that autothrust starts to reduce thrust toward IDLE.

- **At 10 ft, "RETARD" callout comes up:**

  MOVE the thrust levers to IDLE.

  Autothrust disconnects.

- **At touchdown:**

  CHECK that "ROLL OUT" appears on the FMA.

  Note: In the case of tailwind during an automatic rollout, it is recommended to use manual braking without delay or automatic braking for an optimised runway centerline tracking.

- **At the end of the Rollout:**

  Disengage the autopilot.

  If an AP is not disengaged at the end of the rollout, and the pilot uses the nosewheel steering tiller to taxi the aircraft off the runway, the autopilot will steer the aircraft back to the localizer when the tiller is released.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

AUTOLAND

CHECK that the FMA displays the aircraft capability (CAT 2 or CAT 3) for the intended ILS approach.
MONITOR the radio automatic callout.

- **At 350 ft RA:**

  CHECK that "LAND" is displayed on the FMA.

  CHECK ILS course.

  If LAND is not displayed or if the ILS course is not correct, do not perform an autoland. The flight crew should perform a go-around, if visual references are not sufficient.

- **Between 50 and 40 ft RA:**

  CHECK that "FLARE" is displayed on the FMA.

- **At approximately 30 ft RA:**

  CHECK that "IDLE" is displayed on the FMA, and that autothrust starts to reduce thrust toward IDLE.

- **At 10 ft, "RETARD" callout comes up:**

  MOVE the thrust levers to IDLE.

  Autothrust disconnects.

- **At touchdown:**

  CHECK that "ROLL OUT" appears on the FMA.

  Note: In the case of tailwind during an automatic rollout, it is recommended to use manual braking without delay or automatic braking for an optimised runway centerline tracking.

- **At the end of the Rollout:**

  Disconnect the autopilot.

  If the flight crew does not disconnect the AP at the end of the rollout, and uses the nosewheel steering handwheel to taxi the aircraft off the runway, the following will occur:
  - *The AP will try to steer the aircraft back to the runway centerline, if the nosewheel steering handwheel is released and the aircraft heading is less than 20 ° off the runway centerline.*
  - *The AP will automatically disconnect, if the aircraft heading is 20 ° or more off the runway centerline.*

Applicable to: B-HTD, B-HTE, B-HTF

AUTOLAND

CHECK that the FMA displays the aircraft capability (CAT 2 or CAT 3) for the intended ILS approach.
MONITOR the radio automatic callout.

- **At 350 ft RA:**
  CHECK that "LAND" is displayed on the FMA.
  CHECK ILS course.
  If LAND is not displayed or if the ILS course is not correct, do not perform an autoland. The flight crew should perform a go-around, if visual references are not sufficient.
- **Between 50 and 40 ft RA:**
  CHECK that "FLARE" is displayed on the FMA.
- **At approximately 30 ft RA:**
  CHECK that "IDLE" is displayed on the FMA, and that autothrust starts to reduce thrust toward IDLE.
- **At 10 ft, "RETARD" callout comes up:**
  MOVE the thrust levers to IDLE.
  Autothrust disconnects.
- **At touchdown:**
  CHECK that "ROLL OUT" appears on the FMA.
- **At the end of the Rollout:**
  Disengage the autopilot.
  If an AP is not disengaged at the end of the rollout, and the pilot uses the nosewheel steering tiller to taxi the aircraft off the runway, the autopilot will steer the aircraft back to the localizer when the tiller is released.

Applicable to: B-HTG, B-HTH, B-HTI

AUTOLAND

CHECK that the FMA displays the aircraft capability (CAT 2 or CAT 3) for the intended ILS approach.
MONITOR the radio automatic callout.

- **At 350 ft RA:**
  CHECK that "LAND" is displayed on the FMA.

CHECK ILS course.

If LAND is not displayed or if the ILS course is not correct, do not perform an autoland. The flight crew should perform a go-around, if visual references are not sufficient.

- **Between 50 and 40 ft RA:**

  CHECK that "FLARE" is displayed on the FMA.

- **At approximately 30 ft RA:**

  CHECK that "IDLE" is displayed on the FMA, and that autothrust starts to reduce thrust toward IDLE.

- **At 10 ft, "RETARD" callout comes up:**

  MOVE the thrust levers to IDLE.

  Autothrust disconnects.

- **At touchdown:**

  CHECK that "ROLL OUT" appears on the FMA.

- **At the end of the Rollout:**

  Disconnect the autopilot.

  If the flight crew does not disconnect the AP at the end of the rollout, and uses the nosewheel steering handwheel to taxi the aircraft off the runway, the following will occur:
  - *The AP will try to steer the aircraft back to the runway centerline, if the nosewheel steering handwheel is released and the aircraft heading is less than 20 ° off the runway centerline.*
  - *The AP will automatically disconnect, if the aircraft heading is 20 ° or more off the runway centerline.*

Applicable to: ALL

MANUAL LANDING

- **At DH:**

  DISCONNECT the APs. SPEED mode remains engaged.

- **At 20 ft "RETARD" automatic call out comes up:**

  MOVE the thrust levers to IDLE if they are not there already. (The A/THR disconnects).

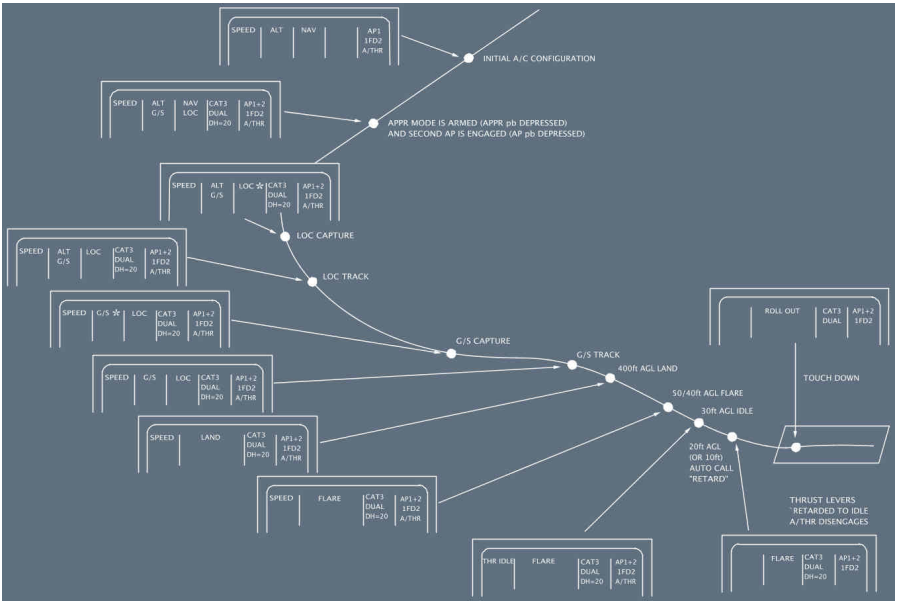
- **At touch down:**

  "ROLL OUT" appears on the FMA and the yaw bar comes up on the PFD.

  Note: *The retard call out is only a reminder when a manual landing is performed.*

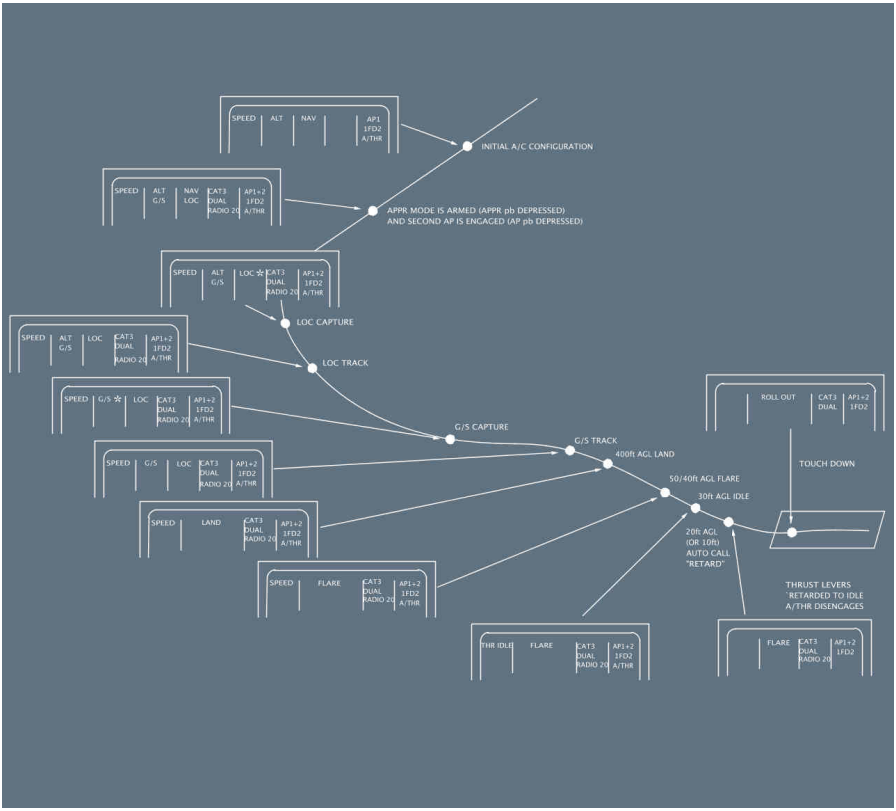
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

STANDARD ILS AUTOMATIC APPROACH



Applicable to: B-HSQ, B-HSR

STANDARD ILS AUTOMATIC APPROACH



Applicable to: ALL

EARLY SELECTION OF APPROACH MODE LOC-G/S

Pressing the APPR pushbutton arms LOC and G/S.
The RA signal is not valid above 8 200 ft AGL (TRT), or 5 000 ft AGL (Collins) or 7 900 ft AGL (Honeywell).

- **If the aircraft is cleared for an ILS approach, when it is higher than 8 200 ft AGL (TRT), or 5 000 ft AGL (Collins), or 7 900 ft AGL (Honeywell), proceed as follows:**
  PRESS the APPR pushbutton on the FCU.

- **When aligned on the localizer, check LOC and G/S engagement:**

  CAT 1 is displayed on the FMA. (Radio altimeters not yet valid).

  Check that the FMA displays the correct capability for the intended approach, when the aircraft is below 5 000 ft AGL.

Applicable to: B-HSD, B-HSE, B-HSG, B-HTF

GLIDESLOPE INTERCEPTION FROM ABOVE

If the aircraft is above the glideslope, the system will not capture the G/S automatically.
The pilot must bring the aircraft onto the glideslope beam, and select an appropriate V/S to intercept it. *Refer to 00011571 **Not found**.*

CAUTION	If the pilot selects too great a V/S, he could increase the current speed to VMAX (VFE), which will result in a mode reversion. If this occurs, with an FCU altitude set above the aircraft altitude, then OPEN CLB will engage.

Applicable to: B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTG, B-HTH, B-HTI

GLIDESLOPE INTERCEPTION FROM ABOVE

If the aircraft is above the glideslope, the system will not capture the G/S automatically.
The pilot must bring the aircraft onto the glideslope beam, and select an appropriate V/S to intercept it. *Refer to 00011571 **Not found**.*

Applicable to: ALL

DATA LOCK

When the aircraft reaches 700 ft RA with APPR mode (LOC and G/S) armed or engaged, the ILS FREQ and course are frozen in the receiver.
This function (ILS tune inhibit) is available, when at least one AP/FD is engaged. Any attempt to change the ILS frequency or CRS, via the MCDU or RMP, does not affect the receiver.
If the speed is managed, the system does not accept any modifications the pilot may enter on the PERF APPR page (surface wind, selected landing configuration, or VAPP) for speed guidance purposes below this altitude.
When the aircraft reaches 400 ft RA, LAND mode engages. The flight crew can only disengage this mode by engaging the GO AROUND mode.

Applicable to: ALL

USE OF RMPS FOR ILS/DME

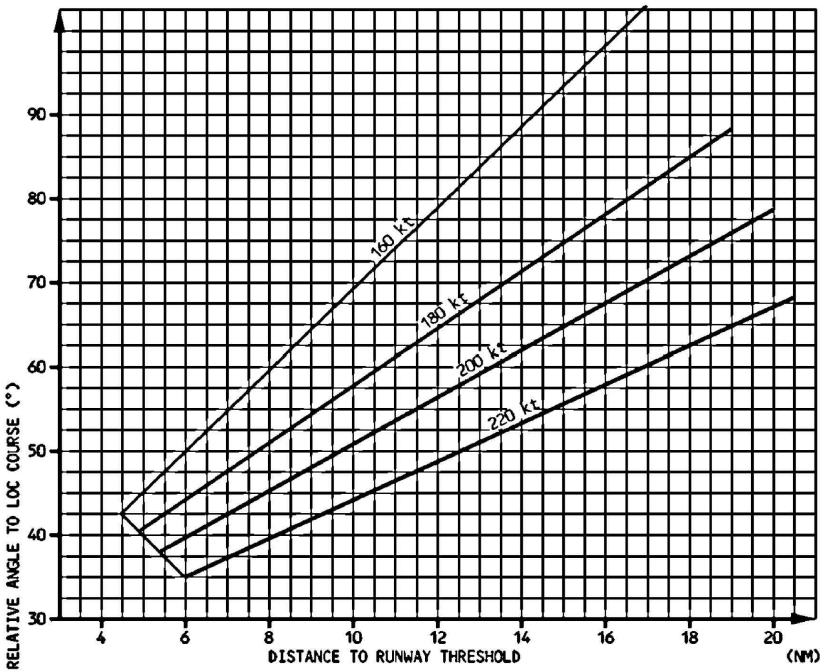
If both FMGCs fail, the flight crew can use the RMPs (Radio Management Panels 1 and 2) for back up tuning. Either RMP controls ILS. Prior to select an ILS frequency on one of the RMPs, the flight crew has to select “NAV”button from RMP 1 and RMP 2.

If the ILS has a DME, the PFD will not display the DME distance. In this situation, the flight crew will fly without DME information. If necessary, increase the Decision height (DH) accordingly.

Applicable to: ALL

LOCALIZER (LOC) BEAM CAPTURE

The flight crew must always monitor the capture of a LOC beam. During this evolution, the PFD and ND must indicate that associated deviation indications move toward the centre of the scale. To avoid performing a false capture, the flight crew must be careful not to arm the LOC too early. The following graph shows the angle of interception versus distance to the runway threshold that ensures that the aircraft will not overshoot the axis by more than one and a half dot.



The capture begins when the deviation is two dots or less. It is programmed to line the aircraft up on the beam with a single overshoot, even if the intercept angle is large.

Note: *ICAO requires LOC beam to ensure a normal capture within 10 nm and plus or minus 35 ° from the course centerline. Some ILS systems just meet the requirement and are subject to false capture outside these limits.*

SWITCHING FROM NON ILS TO ILS APPROACH

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

If an ILS approach is possible when a non ILS was previously scheduled, use one of the following procedures:

USE OF SECOND FLIGHT PLAN

Use a secondary flight plan to prepare the alternate ILS approach, time permitting.

COPY the ACTIVE flight plan.
REVISE the ARRIVAL: insert the ILS approach and the applicable STAR/VIA.
On the RAD NAV page, TUNE in the ILS manually.
REVISE the PERF APPR page.

CHANGE OF THE CLEARANCE

ATC changes the clearance from the non-ILS to the ILS approach.

- **If a secondary flight plan has been prepared:**
  ACTIVATE the SEC F-PLN and adjust.
  Follow subsequent standard procedures.
- **If a secondary flight plan has not been prepared:**
  REVISE the ARRIVAL on the primary F-PLN, inserting the ILS approach.
  REVISE the PERF APPR page.
  Follow subsequent standard procedures.

CAUTION	If the pilot decides to fly the ILS approach without revising the arrival of the primary flight plan (a non ILS approach is in the F-PLN), LOC and G/S modes will not be available when he presses the APPR pushbutton. Consequently, he should: • Manually TUNE in the ILS on the RAD NAV page: CHECK that the "CHECK APPR GUIDANCE" message comes up. • Press the ILS pushbutton and select ROSE ILS on the EIS CONTROL panel. • Use HDG, V/S or TRK, FPA modes to fly the ILS.

SWITCHING FROM NON ILS TO ILS APPROACH

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

If an ILS approach is possible when a non ILS was previously scheduled, use one of the following procedures:

USE OF SECOND FLIGHT PLAN

Use a secondary flight plan to prepare the alternate ILS approach, time permitting.

COPY the ACTIVE flight plan.
REVISE the ARRIVAL: insert the ILS approach and the applicable STAR/VIA.
On the RAD NAV page, TUNE in the ILS manually.
REVISE the PERF APPR page.

CHANGE OF THE CLEARANCE

ATC changes the clearance from the non-ILS to the ILS approach.

- **If a secondary flight plan has been prepared:**

  ACTIVATE the SEC F-PLN and adjust.

  Follow subsequent standard procedures.

- **If a secondary flight plan has not been prepared:**

  REVISE the ARRIVAL on the primary F-PLN, inserting the ILS approach.

  REVISE the PERF APPR page.

  Follow subsequent standard procedures.

CAUTION	If the pilot decides to fly the ILS approach without revising the arrival of the primary flight plan (a non ILS approach is in the F-PLN), LOC and G/S modes will not be available when he presses the APPR pushbutton. Consequently, he should: • Manually TUNE in the ILS on the RAD NAV page: CHECK that the "CHECK APPR SELECTION" message comes up. • Press the ILS pushbutton and select ROSE ILS on the EIS CONTROL panel. • Use HDG, V/S or TRK, FPA modes to fly the ILS.

TASK SHARING DURING CAT I, CAT II AND CAT III APPROACH AND LANDING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

LIM-22-20 section of this FCOM provides all limitations regarding CAT I, CAT II, and CAT III approaches and landings. This includes precautions to be taken when performing autoland on CAT I ILS beam with good visibility.

Anytime a precision approach is performed the PM must announce that a flight parameter is being exceeded, if:

- During glide beam capture:
  - Pitch attitude becomes less than -2.5 ° or greater than +10 ° (nose up).
  - Vertical speed exceeds + 500 ft/min or -1 250 ft/min.
- During final approach:
  - Speed goes below speed target - 5 kt or above speed target + 10 kt (“SPEED”)
  - Pitch attitude goes below -2.5 ° or above 10 ° (“PITCH”)
  - Bank angle becomes greater than 7 ° (“BANK”)
  - Descent rate becomes greater than 1 000 ft/min (“SINK RATE”)
  - There is too much LOC or GLIDE deviation (“LOCALIZER”or “GLIDE”).

If the flight crew suspects that autopilot guidance is not effective, they should:

- Use the instinctive disconnect pushbutton to disconnect the autopilot, or
- Perform an automatic go-around.

The flight crew may perform a CAT II/CAT III approach, if:

- The FMA displays the corresponding category
- The required systems and functions are operative
- The airport is approved for the intended operations
- They are qualified to perform the specific approach.

CAT III APPROACH

AUTO CALL OUT RA is mandatory.
A/THR in SPEED MODE is mandatory.

Note: AUTO CALL OUT is not mandatory for CAT 2 approach: The PM may perform this function.

TASK SHARING DURING CAT I, CAT II AND CAT III APPROACH AND LANDING

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

LIM-22-20 section of this FCOM provides all limitations regarding CAT I, CAT II, and CAT III approaches and landings. This includes precautions to be taken when performing autoland on CAT I ILS beam with good visibility.

Anytime a precision approach is performed the PM must announce that a flight parameter is being exceeded, if:

- During glide beam capture:
  - Pitch attitude becomes less than -2.5 ° or greater than +7.5 ° (nose up).
  - Vertical speed exceeds + 500 ft/min or -1 250 ft/min.
- During final approach:
  - Speed goes below speed target - 5 kt or above speed target + 10 kt (“SPEED”).
  - Pitch attitude goes below -2.5 ° or above +7.5 ° (“PITCH”)
  - Bank angle becomes greater than 7 ° (“BANK”)
  - Descent rate becomes greater than 1 000 ft/min (“SINK RATE”)
  - There is too much LOC or GLIDE deviation (“LOCALIZER”or “GLIDE”).

If the flight crew suspects that autopilot guidance is not effective, they should:

- Use the instinctive disconnect pushbutton to disconnect the autopilot, or
- Perform an automatic go-around.

The flight crew may perform a CAT II/CAT III approach, if:

- The FMA displays the corresponding category
- The required systems and functions are operative
- The airport is approved for the intended operations
- They are qualified to perform the specific approach.

CAT III APPROACH

AUTO CALL OUT RA is mandatory.
A/THR in SPEED MODE is mandatory.

Note: AUTO CALL OUT is not mandatory for CAT 2 approach: The PM may perform this function.

TASK SHARING FOR CAT I APPROACH (OR BETTER)

Monitor thrust reduction and flare by flight instruments	Monitor auto callouts
•At 10 ft RA	
Auto callout ″RETARD″	
RETARD both thrust levers to IDLE	Monitor engines parameters
Monitor lateral guidance by external reference	
• <u>At TOUCH DOWN</u>	
	Check ROLL OUT on FMA and announce
Select and control reverse thrust	Check reverse green and announce Announce 70 kt
Disengage the APs at the end of the Roll out (when leaving the runway at the latest)	
•If external visual references are <u>not</u> sufficient	
″GO-AROUND, FLAPS″and execute	

TASK SHARING FOR CAT III APPROACH/LANDING WITHOUT DH

Applicable to: ALL

PF	PM
•At 350 ft RA	
Check ILS course on PFD	
″LAND GREEN″when displayed on FMA	"Check"
•At 100 ft RA	
If no failure is detected, ″CONTINUE″	Monitor auto callout *(1)*
•At 40 ft RA	
	Check FLARE on FMA and announce
•At 30 ft RA	
Monitor thrust reduction and flare by flight instruments	Monitor auto callout *(1)*

Continued on the following page

Continued from the previous page

PF	PM
•At 10 ft RA	
AUTO CALL OUT "RETARD"	
RETARD both thrust levers to IDLE	Monitor engines parameters
Monitor lateral guidance by external reference	
• At TOUCH DOWN	
	CHECK ROLL OUT on FMA and announce
Select and control reverse thrust	Check reverse green and announce
	Announce 70 kt
Disengage the APs at the end of the Roll out (when leaving the runway at the latest)	

(1) In case of CAT III without DH, the pilot should enter "NO" in the DH field of the MCDU to avoid false "HUNDRED ABOVE" or "MINIMUM" auto callouts which would not be applicable.

LANDING CATEGORIES

Applicable to: ALL

Each FMGC computes its own landing category : CAT1, CAT2, CAT3 single, and CAT3 dual and displays the corresponding landing category on the FMAs.
Each category depends upon the availability of aircraft systems and functions.
When the landing capability downgrades, a triple click aural warning is activated.

FAIL-OPERATIONAL AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-operational if, in the event of a failure below alert height, the remaining part of the automatic system allows the aircraft to complete the approach, flare, and landing. A CAT 3 DUAL system is a fail-operational automatic landing system.

Note: In the event of a failure, the automatic landing system operates as a fail-passive system.

FAIL-PASSIVE AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-passive if, in the event of a failure, there is no significant out-of-trim condition or deviation of flight path or attitude, but the landing is not completed automatically. A CAT3 single system is a fail-passive automatic landing system.

Note: With a fail-passive automatic landing system the pilot assumes control of the aircraft after a failure.

Below 100 ft (radio altimeter), the FMGS freezes the landing capability until LAND mode is disengaged or both APs are off.
Therefore a failure occurring below 100 ft does not change the category of the system.

ALERT HEIGHT

The alert height is the height above touch down, above which a CAT3 autoland would be discontinued and a missed approach executed, if a failure occurred in either the airplane systems or the relevant ground equipments.
Below the alert height, if such a failure occurs, the flare, touchdown and roll out may be accomplished using the remaining automatic system.

WARNINGS FOR ILS APPROACH

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

AUTOLAND WARNING

With “LAND” or “FLARE” green on the FMA and at least one AP engaged, the AUTOLAND red light appears on the glareshield when the aircraft is below 200 ft RA and one of the following events occurs:
- The autopilots are lost, or
- The aircraft gets too far off the beam (LOC or G/S flash on PFD), or
- Loss of LOC signal above 15 ft, or loss of glide signal above 100 ft (transmitter or receivers).
- The difference between both radio altimeter indications is greater than 15 ft.

When the Autoland light comes on, Autoland must be discontinued (*Refer to PRO-NOR-SRP-01-70 FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT DURING A CAT II APPROACH*,
Refer to PRO-NOR-SRP-01-70 FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT CAT III WITH DH,
Refer to PRO-NOR-SRP-01-70 Failures and Associated Actions Below 1 000 ft for CAT III without DH).

WARNING OF EXCESSIVE BEAM DEVIATION

This warning is a flashing of the LOC and G/S scales on the PFD and ND ROSE ILS. It occurs whenever:
- G/S deviation is greater than 1 dot (above 100 ft RA).
- LOC deviation is greater than 1/4 dot (above 15 ft RA).

WARNING ASSOCIATED WITH ILS "LANDING CAPABILITY"

Any downgrading in the aircraft’s capability for automatic approach and landing sounds a triple-click aural warning.

FAILURE OF BOTH LOCALIZER AND GLIDESLOPE RECEIVERS

The PFD and ND (rose ILS mode) display red LOC and G/S flags (if the ILS pushbutton has been pressed green). LOC and G/S scales disappear from the PFD.

If LOC or G/S modes are engaged and at least one AP/FD is engaged
- The AP disengages.
- The FD reverts to its HDG-V/S or TRK-FPA modes.

FAILURE OF LOCALIZER OR GLIDESLOPE TRANSMITTER (WHEN CAPTURED)

- The corresponding index is lost.
- The LOC and G/S scales flash.
- The corresponding FD bar flashes.

The FMA retains the LOC and G/S modes: If the transmitter failure is temporary, the APs are able to regain these modes. If the failure is long-term, or if it occurs when the aircraft is below 200 ft RA, this allows the aircraft to perform a GO AROUND with one or 2 autopilots engaged.

WARNINGS FOR ILS APPROACH

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

AUTOLAND WARNING

With “LAND” or “FLARE” green on the FMA and at least one AP engaged, the AUTOLAND red light appears on the glareshield when the aircraft is below 200 ft RA and one of the following events occurs:
- The autopilots are lost, or
- The aircraft gets too far off the beam (LOC or G/S flash on PFD), or
- Loss of LOC signal above 15 ft, or loss of glide signal above 100 ft (transmitter or receivers).
- The difference between both radio altimeter indications is greater than 15 ft.

When the Autoland light comes on, Autoland must be discontinued (*Refer to PRO-NOR-SRP-01-70 FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT DURING A CAT II APPROACH*,
Refer to PRO-NOR-SRP-01-70 FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT CAT III WITH DH,
Refer to PRO-NOR-SRP-01-70 Failures and Associated Actions Below 1 000 ft for CAT III without DH).

WARNING OF EXCESSIVE BEAM DEVIATION

This warning is a flashing of the LOC and G/S scales on the PFD and ND ROSE ILS. It occurs whenever:
- G/S deviation is greater than 1 dot (above 100 ft RA).
- LOC deviation is greater than 1/4 dot (above 15 ft RA).

WARNING ASSOCIATED WITH ILS "LANDING CAPABILITY"

Any downgrading in the aircraft's capability for automatic approach and landing sounds a triple-click aural warning.

FAILURE OF BOTH LOCALIZER AND GLIDESLOPE RECEIVERS

The PFD and ND (rose ILS mode) display red LOC and G/S flags (if the ILS pushbutton has been pressed green). LOC and G/S scales disappear from the PFD.

If LOC or G/S modes are engaged and at least one AP/FD is engaged
- The AP disengages.
- The FD reverts to its HDG-V/S or TRK-FPA modes.

FAILURE OF LOCALIZER OR GLIDESLOPE TRANSMITTER (WHEN CAPTURED)

- The corresponding index is lost.
- The LOC and G/S scales flash.
- The corresponding FD bar flashes.

Above 200 ft RA, if the transmitter failure lasts less than 7 s, the FMA retains the LOC and G/S modes (or the LAND mode) and the APs are able to regain these modes. If the failure lasts longer than 7 s, the AP disengages and the FD reverts to its basic modes. Below 200 ft RA, if the transmitter failure occurs, the AUTOLAND warning appears, indicating that the crew must perform a GO AROUND (if insufficient visual references) with one or 2 APs engaged.

FAILURES AND ASSOCIATED ACTIONS ABOVE 1 000 FT FOR CAT II OR CAT III

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FAILURE (for multiple failures, the most limiting applies)	ACTION TO BE PERFORMED ABOVE 1 000 ft	LANDING CATEGORY
ONE ENGINE OUT	Complete ECAM procedure.	CAT III SINGLE
LANDING CAPABILITY DECREASE	Try to recover	As displayed on FMA
LOSS OF A/THR	Switch AP, and try to reengage	CAT II (if A/THR not recovered)
NOSE WHEEL STEERING		CAT III SINGLE (DH = 50 ft) Disengage AP at touch down
ANTI SKID		CAT III SINGLE Disengage AP at touch down

Continued on the following page

Continued from the previous page

FAILURE (for multiple failures, the most limiting applies)	ACTION TO BE PERFORMED ABOVE 1 000 ft	LANDING CATEGORY
AMBER "CHECK ATT"ON TWO PFDs	Check with standby horizon, use switching to recover (no switching below 1 000 ft)	CAT III SINGLE (if the warning disappears) CAT I (if not)
AMBER "CHECK HDG"ON TWO PFDs AND TWO NDs	Check with standby compass, use switching to recover (no switching below 1 000 ft)	
RED "HDG"ON ONE PFD AND ONE ND	Use switching to recover (no switching below 1 000 ft)	
RED "ATT"ON ONE PFD		
RED "SPD"ON ONE PFD		
DIAGONAL LINE ON ONE PFD AND ONE ND	Use switching to recover (no switching below 1 000 ft)	CAT III DUAL (if the diagonal line disappears) CAT I (if not)
RED "RA"ON TWO PFDs	AP and FD not available	CAT I (minimum RVR as per regulation)
SLATS/FLAPS FAILURE (LESS THAN CONF 3)		CAT I Disengage AP at or above 500 ft

FAILURES AND ASSOCIATED ACTIONS ABOVE 1 000 FT FOR CAT II OR CAT III

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

FAILURE (for multiple failures, the most limiting applies)	ACTION TO BE PERFORMED ABOVE 1 000 ft	LANDING CATEGORY
ONE ENGINE OUT	Complete ECAM procedure.	CAT III SINGLE
LANDING CAPABILITY DECREASE	Try to recover	As displayed on FMA
LOSS OF A/THR	Switch AP, and try to reengage	CAT II (if A/THR not recovered)
NOSE WHEEL STEERING		CAT III SINGLE (DH = 50 ft) Disengage AP at touch down
ANTI SKID		CAT III SINGLE Disengage AP at touch down

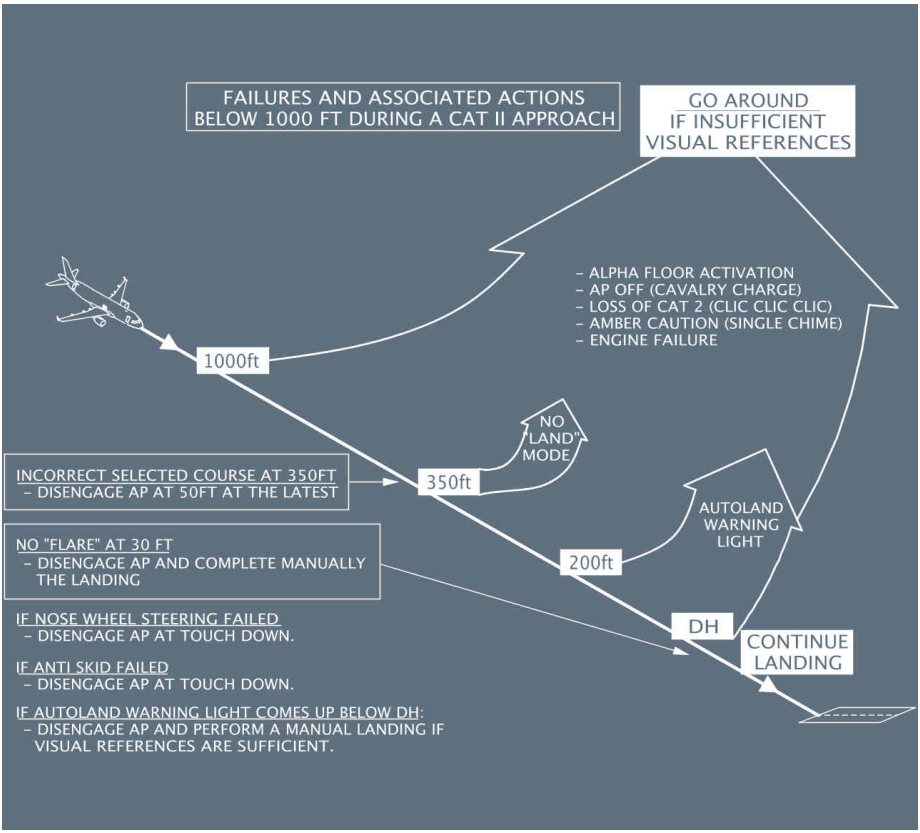
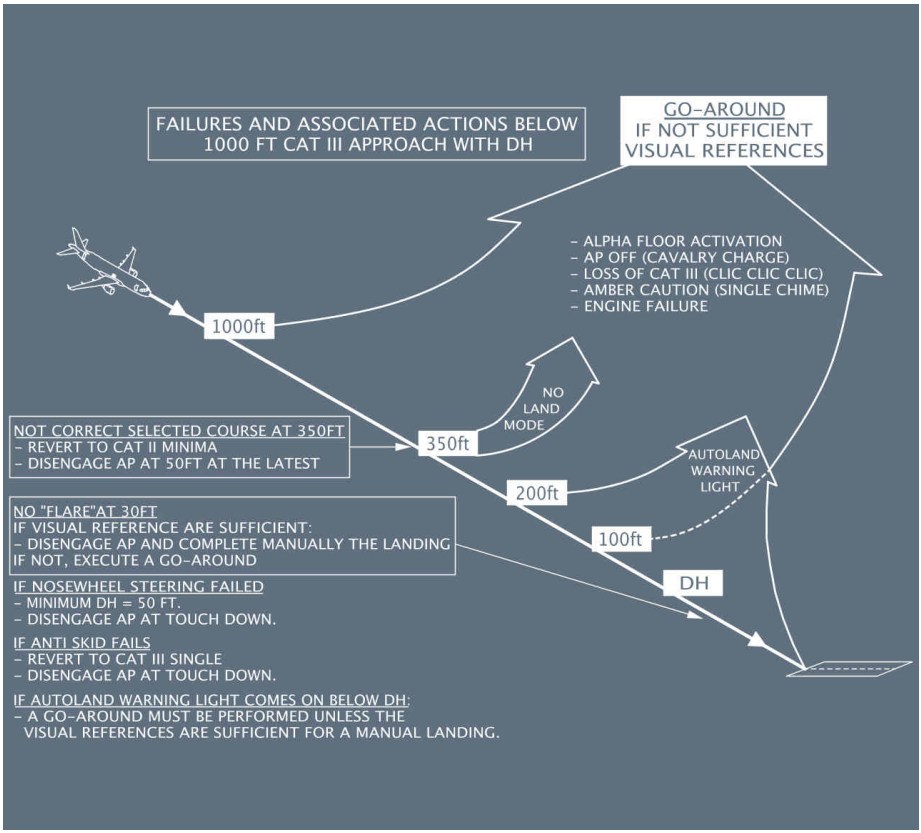
FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT DURING A CAT II APPROACH

Applicable to: ALL



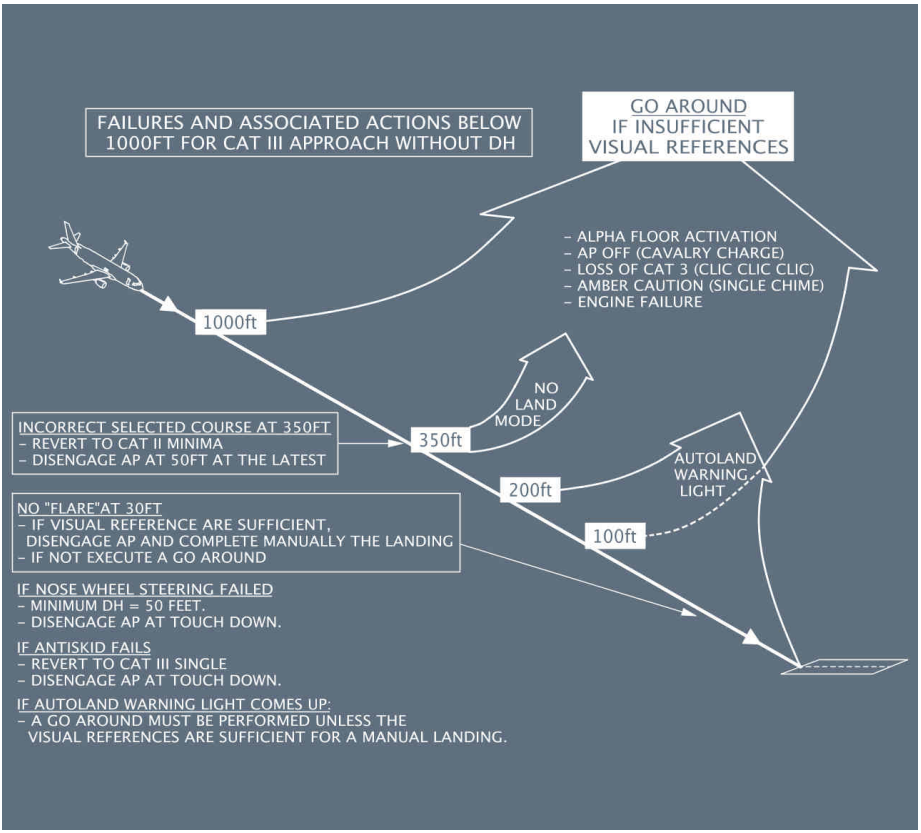
FAILURES AND ASSOCIATED ACTIONS BELOW 1000 FT CAT III WITH DH

Applicable to: ALL



FAILURES AND ASSOCIATED ACTIONS BELOW 1 000 FT FOR CAT III WITHOUT DH

Applicable to: ALL



BACK-COURSE LOCALIZER APPROACH - PROCEDURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

The pilot must fly a back-course localizer approach with the ND in its ILS rose mode.

PROCEDURE

PRESS the RAD NAV key.

ENTER the ILS IDENT.

If the ILS is in the database, the system tunes the proper frequency and the front course.

Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

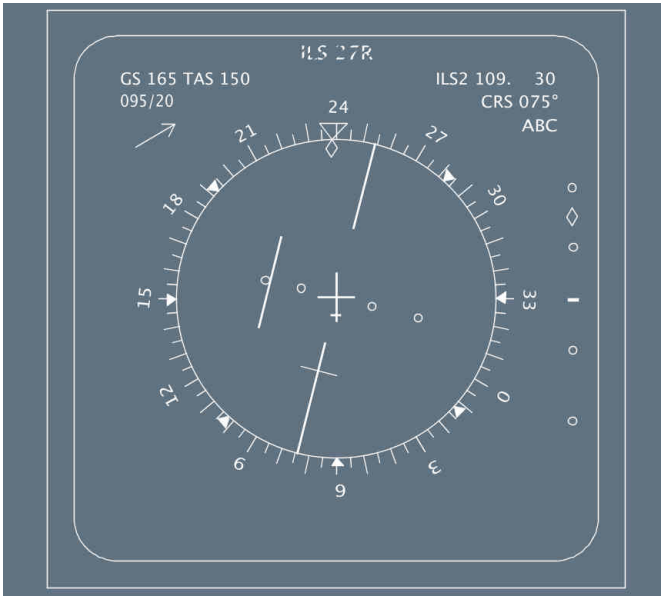
SET the appropriate frequency and SET the FRONT CRS in the CRS field.

On the EFIS control panel, SELECT the ILS ROSE mode.

The display shows the correct LEFT/RIGHT information for the beam deviation.

CAUTION	*DO NOT select ILS via the ILS pushbutton: Doing so makes the PFD show reverse deviations.* *DO NOT arm the LOC or APPR modes.*

The flight director may be used with the TRK-FPA or HDG-V/S modes.



BACK-COURSE LOCALIZER APPROACH - PROCEDURE

Applicable to: B-HSJ, B-HSK, B-HTG, B-HTH, B-HTI

The pilot must fly a back-course localizer approach with the ND in its ILS rose mode.

PROCEDURE

PRESS the RAD NAV key.
ENTER the ILS IDENT.

If the ILS is in the database, the system tunes the proper frequency and the front course.

Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

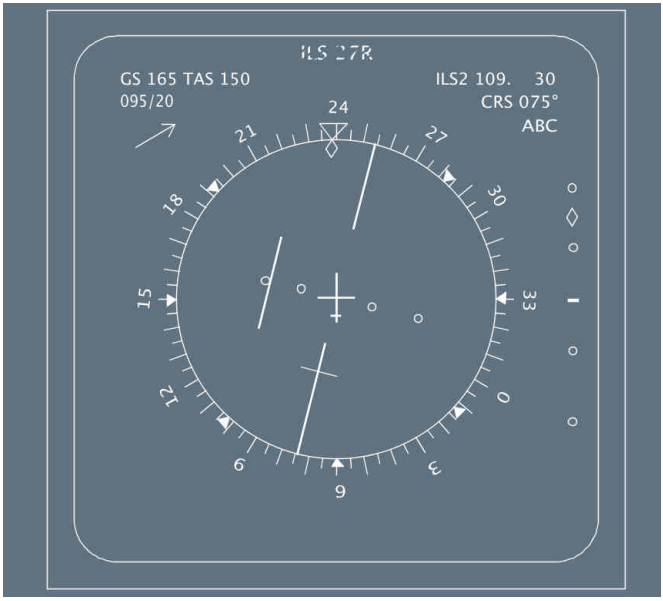
  SET the appropriate frequency and SET the FRONT CRS in the CRS field.

  On the EFIS control panel, SELECT the ILS ROSE mode.

  The display shows the correct LEFT/RIGHT information for the beam deviation.

CAUTION	*DO NOT select ILS via the LS pushbutton: Doing so makes the PFD show reverse deviations.* *DO NOT arm the LOC or APPR modes.*

The flight director may be used with the TRK-FPA or HDG-V/S modes.



BACK-COURSE LOCALIZER APPROACH - PROCEDURE

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The pilot must fly a back-course localizer approach with the ND in its ILS rose mode.

PROCEDURE

PRESS the RAD NAV key.
ENTER the ILS IDENT.
If the ILS is in the database, the system tunes the proper frequency and the front course.

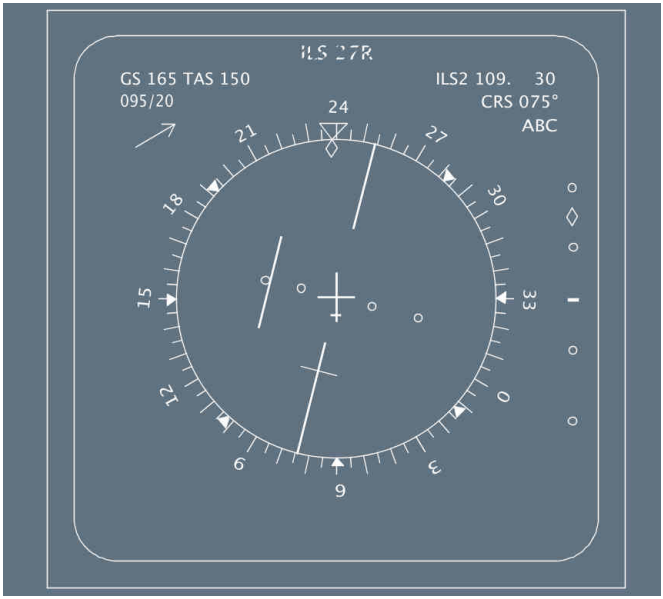
Note: This may trigger the "RWY/ILS MISMATCH" message. Disregard it.

- **If the ILS is not in the database:**

  SET the appropriate frequency and SET the FRONT CRS in the CRS field.
  On the EFIS control panel, SELECT the ILS ROSE mode.
  The display shows the correct LEFT/RIGHT information for the beam deviation.

CAUTION	*DO NOT select ILS via the LS pushbutton: Doing so makes the PFD show reverse deviations.* *DO NOT arm the LOC or APPR modes.* *DO NOT select the LS pushbutton on ISIS, since it displays the LOC deviations in the wrong sense.*

  The flight director may be used with the TRK-FPA or HDG-V/S modes.



NON PRECISION APPROACH

Applicable to: ALL

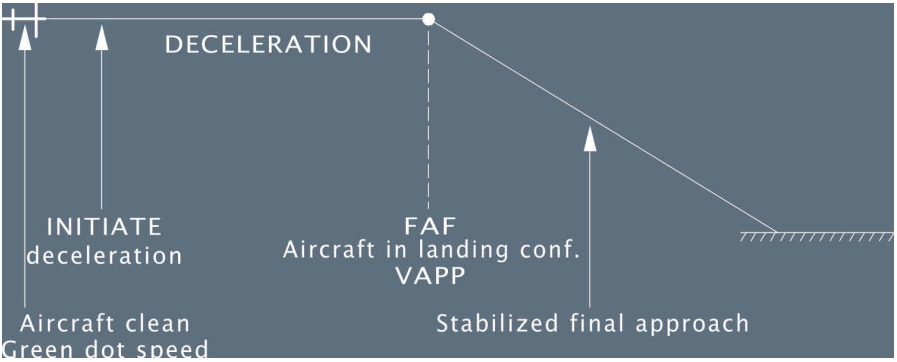
APPROACH SPEED TECHNIQUE

A stabilized approach procedure may be used to perform non precision approaches.

Applicable to: ALL

STABILIZED APPROACH

The “stabilized approach” brings the aircraft to intercept the final descent path in the landing configuration and at VAPP.
Managed speed is best for the stabilized approach and VAPP should be inserted as a speed constraint at the final approach fix.



Applicable to: B-HSD, B-HSE

MANAGED NON PRECISION APPROACH

The Non Precision Approach (NPA) can be flown in lateral and vertical managed guidance (FINAL APP), or in lateral managed guidance (NAV) associated with selected vertical guidance (FPA of V/S).

Note: *For the conditions for using these AP modes, Refer to LIM-22-10 Auto Pilot Function and Refer to PRO-NOR-SOP-19-Introduction - guidance for Non Precision Approaches, other than LOC and RNAV Non Precision Approaches.*

APPROACH PREPARATION

SELECT the intended approach on the F-PLN page.

Check the FM lateral and vertical flight path against the published approach chart, using the MCDU and the ND PLAN mode with constraints displayed.

ENTER VAPP as SPD constraint at the FAF, with a vertical revision of the F-PLN page.

For an approach in overlay to a conventional approach with radio NAVAID:
SELECT/CHECK that the appropriate NAVAID is selected on the RAD NAV page.

INTERMEDIATE APPROACH

SELECT ROSE NAV or MAP mode and VOR or ADF raw data, as appropriate on the ND.
SELECT TRK/FPA display, when established on the final approach course.
USE managed speed.
KEEP A/THR active.

Note: *For additional recommendations, refer to the dedicated FCOM Bulletin on the use of the FINAL APP mode.*

FINAL APPROACH

- **When cleared for approach:**
  - **If managed lateral and vertical guidance is intended:**

    SELECT APPR pushbutton on the FCU.

    CHECK APP NAV green and FINAL blue on the FMA.

    CHECK that blue descent arrow is displayed on ND at the FAF.

    CHECK that the F-PLN on ND and the V-DEV on PFD are correct.

    After sequencing the FAF:

    CHECK that FINAL APP green is displayed on the FMA.

    CHECK on the ND the TO waypoint, the F-PLN to the MAP and the missed approach procedure (blue line).

    SELECT the go-around altitude on the FCU.

    MONITOR the approach lateral and vertical flight path with the available raw data.

  - **If managed lateral and selected vertical guidance is intended:**

    CHECK NAV and FPA on the FMA.

    Upon reaching the FAF:

    Select a FPA to the final descent path.

    Anticipate the selection of the FPA to smoother the interception of the final descent path.

    After sequencing the FAF:

    CHECK, on the ND, the TO waypoint, the F-PLN to the MAP, and the missed approach procedure (blue line).

    SELECT the go-around altitude on the FCU.

    ADJUST the FPA to fly the intended vertical flight path.

- **At MDA/MDH:**
  - **If visual references are acquired and confirmed by both crewmembers:**

    DISCONNECT the AP and FD and continue visually.

  - **If visual references are not acquired:**

    INITIATE a go-around.

MANAGED NON PRECISION APPROACH

The Non Precision Approach (NPA) can be flown in lateral and vertical managed guidance (FINAL APP), or in lateral managed guidance (NAV) associated with selected vertical guidance (FPA of V/S).

Note: *For the conditions for using these AP modes, Refer to LIM-22-10 Auto Pilot Function and Refer to PRO-NOR-SOP-19-Introduction - guidance for Non Precision Approaches, other than LOC and RNAV Non Precision Approaches.*

APPROACH PREPARATION

SELECT the intended approach on the F-PLN page.

Check the FM lateral and vertical flight path against the published approach chart, using the MCDU and the ND PLAN mode with constraints displayed.

ENTER VAPP as SPD constraint at the FAF, with a vertical revision of the F-PLN page.

For an approach in overlay to a conventional approach with radio NAVAID:
SELECT/CHECK that the appropriate NAVAID is selected on the RAD NAV page.

For RNAV or GPS approach, GPS PRIMARY must be available at the ETA at destination. For more information about this check, *Refer to PRO-NOR-SOP-19-Introduction - guidance for Non Precision Approaches, other than LOC and RNAV Non Precision Approaches*.

INTERMEDIATE APPROACH

SELECT ROSE NAV or MAP mode and VOR or ADF raw data, as appropriate on the ND.

For RNAV or GPS approach:
CHECK that both GPS receivers are operative in NAV mode on the GPS MONITOR page.
CHECK that GPS PRIMARY is available on the PROG PAGE.

SELECT TRK/FPA display, when established on the final approach course.
USE managed speed.
KEEP A/THR active.

Note: *For additional recommendations, refer to the dedicated FCOM Bulletin on the use of the FINAL APP mode.*

FINAL APPROACH

- **When cleared for approach:**
  - **If managed lateral and vertical guidance is intended:**

    SELECT APPR pushbutton on the FCU.

    CHECK APP NAV green and FINAL blue on the FMA.

    CHECK that blue descent arrow is displayed on ND at the FAF.

CHECK that the F-PLN on ND and the V-DEV on PFD are correct.

After sequencing the FAF:

CHECK that FINAL APP green is displayed on the FMA.

CHECK on the ND the TO waypoint, the F-PLN to the MAP and the missed approach procedure (blue line).

SELECT the go-around altitude on the FCU.

MONITOR the approach lateral and vertical flight path with the available raw data.

■ **If managed lateral and selected vertical guidance is intended:**

CHECK NAV and FPA on the FMA.

Upon reaching the FAF:

Select a FPA to the final descent path.

Anticipate the selection of the FPA to smoother the interception of the final descent path.

After sequencing the FAF:

CHECK, on the ND, the TO waypoint, the F-PLN to the MAP, and the missed approach procedure (blue line).

SELECT the go-around altitude on the FCU.

ADJUST the FPA to fly the intended vertical flight path.

● **At MDA/MDH:**

■ **If visual references are acquired and confirmed by both crewmembers:**

DISCONNECT the AP and FD and continue visually.

■ **If visual references are not acquired:**

INITIATE a go-around.

Applicable to: B-HSQ, B-HSR

MANAGED NON PRECISION APPROACH

The Non Precision Approach (NPA) can be flown in lateral and vertical managed guidance (FINAL APP), or in lateral managed guidance (NAV) associated with selected vertical guidance (FPA of V/S).

Note: *For the conditions for using these AP modes, Refer to LIM-22-10 Auto Pilot Function and Refer to PRO-NOR-SOP-19-Introduction - guidance for Non Precision Approaches, other than LOC and RNAV Non Precision Approaches.*

APPROACH PREPARATION

SELECT the intended approach on the F-PLN page.

Check the FM lateral and vertical flight path against the published approach chart, using the MCDU and the ND PLAN mode with constraints displayed.

ENTER VAPP as SPD constraint at the FAF, with a vertical revision of the F-PLN page.

For an approach in overlay to a conventional approach with radio NAVAID:
SELECT/CHECK that the appropriate NAVAID is selected on the RAD NAV page.

For RNAV or GPS approach, GPS PRIMARY must be available at the ETA at destination. For more information about this check, *Refer to PRO-NOR-SOP-19-Introduction - guidance for Non Precision Approaches, other than LOC and RNAV Non Precision Approaches.*

INTERMEDIATE APPROACH

SELECT ROSE NAV or MAP mode and VOR or ADF raw data, as appropriate on the ND.

For RNAV or GPS approach:
CHECK that both GPS receivers are operative in NAV mode on the GPS MONITOR page.
CHECK that GPS PRIMARY is available on the PROG PAGE.

SELECT TRK/FPA display, when established on the final approach course.
USE managed speed.
KEEP A/THR active.

Note: *For additional recommendations, refer to the dedicated FCOM Bulletin on the use of the FINAL APP mode.*

FINAL APPROACH

- **When cleared for approach:**
  - **If managed lateral and vertical guidance is intended:**

    SELECT APPR pushbutton on the FCU.

    CHECK APP NAV green and FINAL blue on the FMA.

    CHECK that blue descent arrow is displayed on ND at the FAF.

    CHECK that the F-PLN on ND and the V-DEV on PFD are correct.

    After sequencing the FAF:

    CHECK that FINAL APP green is displayed on the FMA.

    CHECK on the ND the TO waypoint, the F-PLN to the MAP and the missed approach procedure (blue line).

    SELECT the go-around altitude on the FCU.

    MONITOR the approach lateral and vertical flight path with the available raw data.

■ **If managed lateral and selected vertical guidance is intended:**

CHECK NAV and FPA on the FMA.

Upon reaching the FAF:

Select a FPA to the final descent path.

Anticipate the selection of the FPA to smoother the interception of the final descent path.

After sequencing the FAF:

CHECK, on the ND, the TO waypoint, the F-PLN to the MAP, and the missed approach procedure (blue line).

SELECT the go-around altitude on the FCU.

ADJUST the FPA to fly the intended vertical flight path.

● **At minimum:**

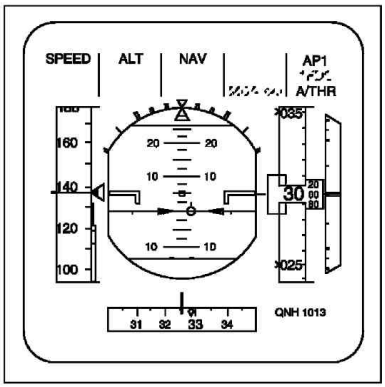
■ **If visual references are acquired and confirmed by both crewmembers:**

DISCONNECT the AP and FD and continue visually.

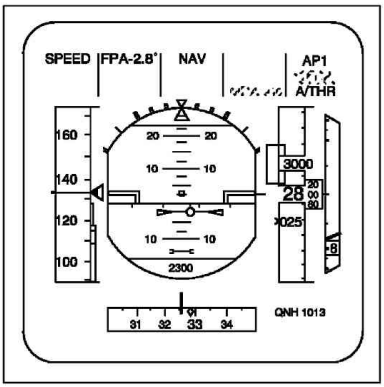
■ **If visual references are not acquired:**

INITIATE a go-around.

Applicable to: ALL

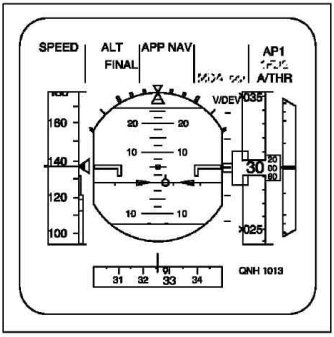


PFD in intermediate approach, FPD and FPV selected. The pilot did not press the APPR pushbutton, the V DEV scale is not displayed.(If GPS is installed, the V DEV scale is displayed when the approach phase is active).

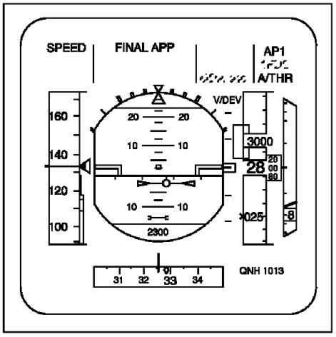


PFD when established on final path: The vertical guidance is the final path angle, as selected by the pilot (FPA); the lateral guidance is computed by the FM (NAV).

Applicable to: ALL



PFD in intermediate approach, FPD and FPV selected. The pilot has pressed the APPR pushbutton, the FINAL managed mode is armed, the V DEV scale is displayed.(If GPS is installed, the V DEV scale is displayed when the approach phase is active).
Each V DEV graduation indicates 100 feet, the rectangle shows the computed vertical path versus the aircraft position.



PFD when established on final path:
The lateral and vertical guidances are managed by the FM (FINAL APP).

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

SELECTED NON PRECISION APPROACH

The non precision approach is flown in selected modes (TRK-FPA or HDG-V/S) when:

- The approach is not stored in the database or
- GPS PRIMARY is lost and the NAV accuracy check is negative.

INTERMEDIATE APPROACH

Procedure

USE TRK-FPA mode
SELECT ND in the ROSE VOR mode
KEEP the autothrust active
USE managed speed

FINAL APPROACH

Upon reaching the final approach fix

SELECT a final approach track on the FCU
SELECT an FPA (flight path angle) to the final descent path angle

Anticipate the selection of FPA to smooth the interception of the final path.

Note: If the pilot is using the AP, select the final FPA approximately 0.3 nm before the final approach fix.

SELECT a go around altitude on FCU.
USE raw data to monitor aircraft position and flight path.

- **AT MDA/MDH:**
  - **If visual references are acquired**
    DISCONNECT the autopilot and continue the approach visually.
  - **If visual references are not acquired**
    INITIATE a go around

NON DIRECTIONAL BEACON (NDB) APPROACH TYPE

When the flight plan calls for an NDB approach, the system automatically tunes the ADF, only when the aircraft is passing the first fix of the approach. Therefore, it is convenient to manually tune the ADF earlier (before activating the approach phase).
Fly a Non Directional Beacon (NDB) approach as any non precision approach.

LOC APPROACH TYPE

SELECT the LOC pushbutton in intermediate approach, to arm the LOC mode.

CAUTION	*Do not select the APPR pushbutton.*

SELECT the ND in ROSE ILS mode.

- **Upon reaching the final approach fix:**
  MONITOR LOC engagement.
  SELECT the FPA to the final descent path angle.

Note: In case of a dual Radio Altimeter (RA) failure, the LOC pb can still be used to arm the LOC mode, as it does not depend on the RA signal.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

SELECTED NON PRECISION APPROACH

The non precision approach is flown in selected modes (TRK-FPA or HDG-V/S) when:
- The approach is not stored in the database or
- GPS PRIMARY is lost and the NAV accuracy check is negative.

INTERMEDIATE APPROACH

Procedure

USE TRK-FPA mode

SELECT ND in the ROSE VOR mode
KEEP the autothrust active
USE managed speed

FINAL APPROACH

Upon reaching the final approach fix

SELECT a final approach track on the FCU
SELECT an FPA (flight path angle) to the final descent path angle

Anticipate the selection of FPA to smooth the interception of the final path.

Note: If the pilot is using the AP, select the final FPA approximately 0.3 nm before the final approach fix.

SELECT a go around altitude on FCU.
USE raw data to monitor aircraft position and flight path.

- **AT MDA/MDH:**
  - **If visual references are acquired**

    DISCONNECT the autopilot and continue the approach visually.
  - **If visual references are not acquired**

    INITIATE a go around

NON DIRECTIONAL BEACON (NDB) APPROACH TYPE

When the flight plan calls for an NDB approach, the system automatically tunes the ADF, only when the aircraft is passing the first fix of the approach. Therefore, it is convenient to manually tune the ADF earlier (before activating the approach phase).
Fly a Non Directional Beacon (NDB) approach as any non precision approach.

LOC APPROACH TYPE

SELECT the LOC pushbutton in intermediate approach, to arm the LOC mode.

CAUTION	*Do not select the APPR pushbutton.*

SELECT the ND in ROSE LS mode.

- **Upon reaching the final approach fix:**

  MONITOR LOC engagement.

  SELECT the FPA to the final descent path angle.

Note: In case of a dual Radio Altimeter (RA) failure, the LOC pb can still be used to arm the LOC mode, as it does not depend on the RA signal.

Applicable to: B-HSQ, B-HSR

SELECTED NON PRECISION APPROACH

The non precision approach is flown in selected modes (TRK-FPA or HDG-V/S) when:
- The approach is not stored in the database or
- GPS PRIMARY is lost and the NAV accuracy check is negative.

INTERMEDIATE APPROACH

Procedure

USE TRK-FPA mode
SELECT ND in the ROSE VOR mode
KEEP the autothrust active
USE managed speed

FINAL APPROACH

Upon reaching the final approach fix

SELECT a final approach track on the FCU
SELECT an FPA (flight path angle) to the final descent path angle

Anticipate the selection of FPA to smooth the interception of the final path.

Note: *If the pilot is using the AP, select the final FPA approximately 0.3 nm before the final approach fix.*

SELECT a go around altitude on FCU.
USE raw data to monitor aircraft position and flight path.

- **At minimum:**
  - **If visual references are acquired**

    DISCONNECT the autopilot and continue the approach visually.
  - **If visual references are not acquired**

    INITIATE a go around

NON DIRECTIONAL BEACON (NDB) APPROACH TYPE

When the flight plan calls for an NDB approach, the system automatically tunes the ADF, only when the aircraft is passing the first fix of the approach. Therefore, it is convenient to manually tune the ADF earlier (before activating the approach phase).
Fly a Non Directional Beacon (NDB) approach as any non precision approach.

LOC APPROACH TYPE

SELECT the LOC pushbutton in intermediate approach, to arm the LOC mode.

CAUTION	*Do not select the APPR pushbutton.*

SELECT the ND in ROSE LS mode.

- **Upon reaching the final approach fix:**

  MONITOR LOC engagement.

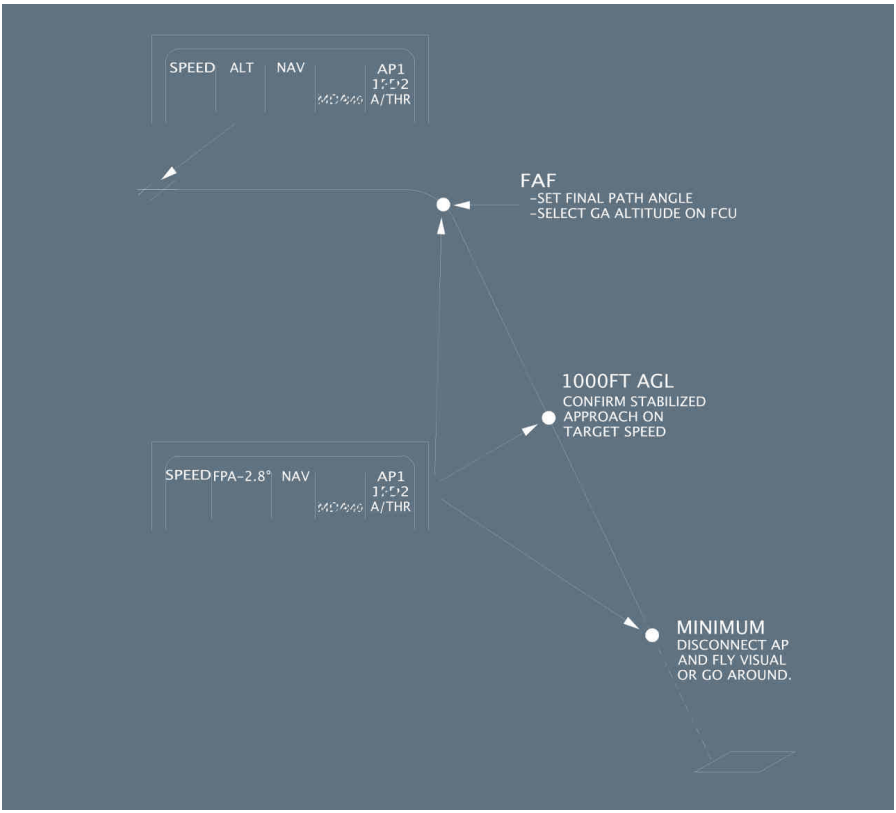
  SELECT the FPA to the final descent path angle.

Note: *In case of a dual Radio Altimeter (RA) failure, the LOC pb can still be used to arm the LOC mode, as it does not depend on the RA signal.*

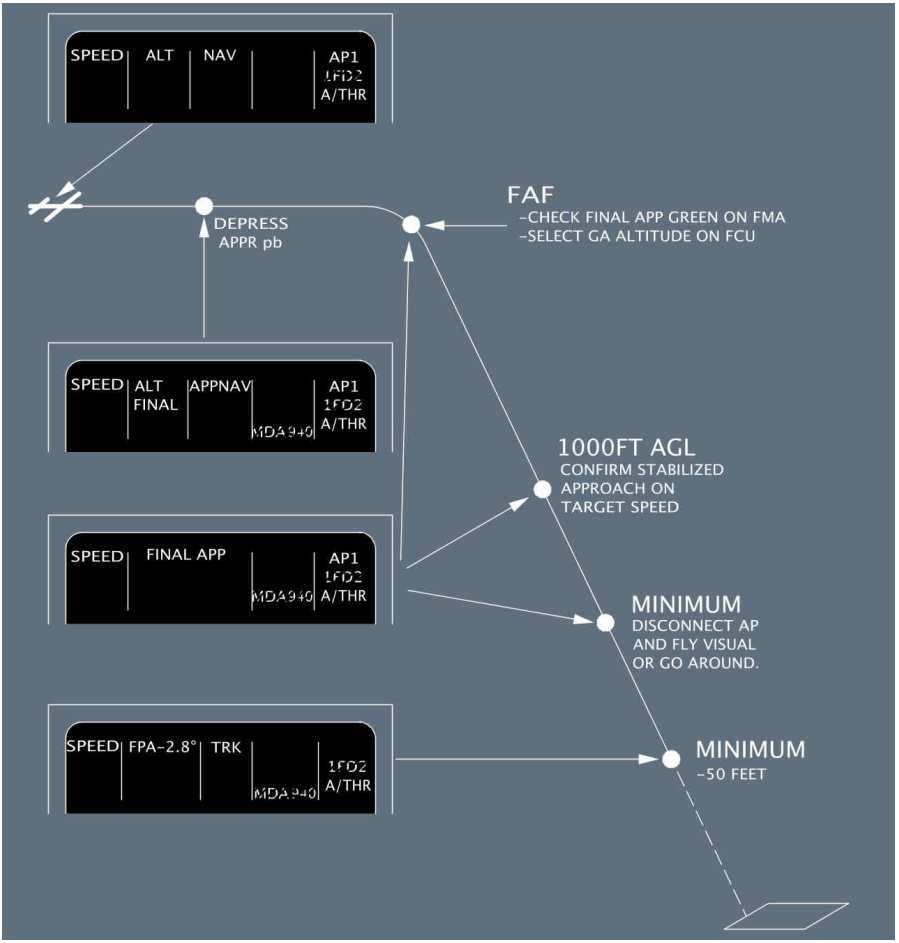
NON PRECISION APPROACH PROFILE

Applicable to: ALL

MANAGED LATERAL AND SELECTED VERTICAL GUIDANCE

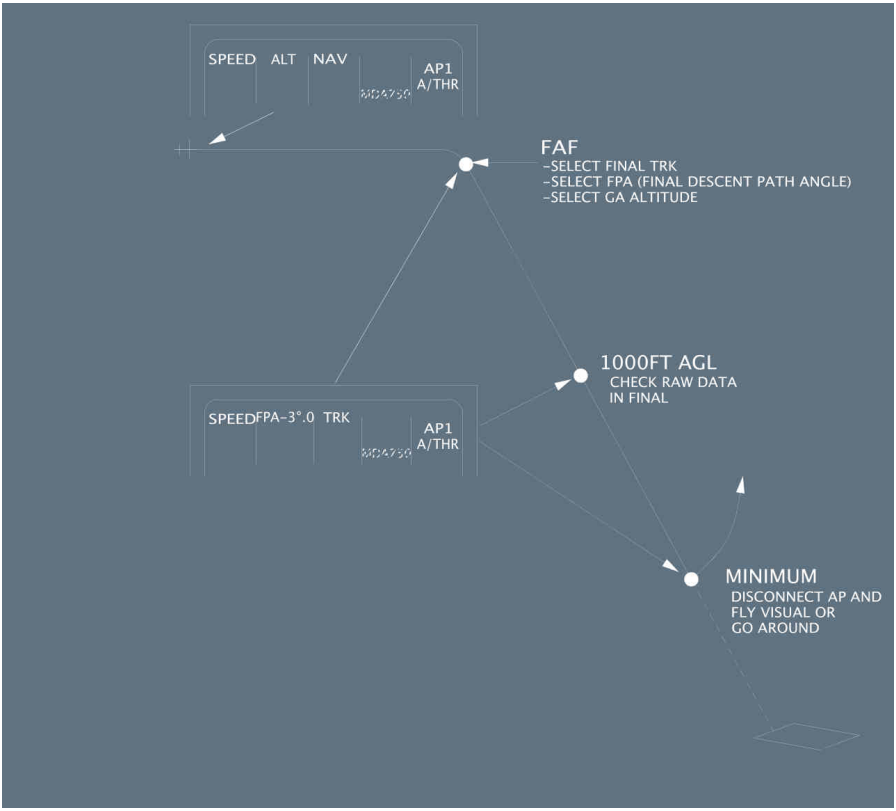


LATERAL AND VERTICAL MANAGED GUIDANCE



CAUTION	When FINAL APP modes are engaged, the AP/FD will disengage: - At the minimum - 50 ft (if entered) or at 400 ft AGL (if no minimum is entered), or - At the Missed Approach Point (MAP), depending on which one comes first. The FDs will revert to basic modes (HDG-V/S or TRK-FPA).

SELECTED GUIDANCE



Note: *If the distance to the runway is not properly assessed, a step descent approach may be considered and a level-off at minimum may be performed while searching for visual references. If the pilot has no visual reference at the MAP, at the latest, he must initiate a go-around.*

CIRCLING APPROACH

Applicable to: ALL

If the pilot chooses not to follow the SOP procedure, select both FDs OFF and fly visually.

If the runway in use is not the flight plan runway, the ground speed and the VAPP will not be computed properly, and the speed on final may be higher than excepted.
Therefore, select the approach speed directly on the FCU.

VISUAL APPROACH

Applicable to: ALL

When flying visual, the pilot may select an appropriate STAR and RWY in use on the MCDU.
The ND displays the extended runway centerline five nautical miles out from the runway.
This helps the pilot during the final turn.
Along with the FPV, the PFD displays a track bug that may help the pilot to fly the downwind leg and intercept final. The FPV should be flown laterally with reference to the track bug.

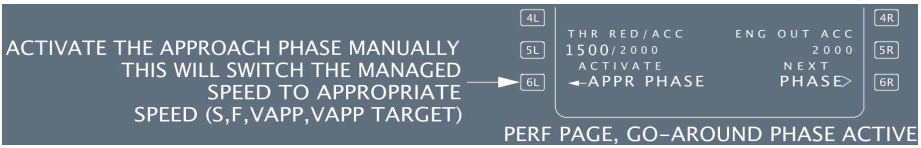
Go-Around

MONITORING THE GO-AROUND

Applicable to: B-HSD, B-HSE, B-HSG, B-HTF

Engage the GO-AROUND phase and GO-AROUND modes by setting the thrust levers to the TOGA position, if at least CONF1 is selected.
When the GO-AROUND phase is engaged, the previously-flown approach is automatically strung back into the flight plan at the end of the missed approach procedure.
In the GO-AROUND phase, the system makes no predictions. Consequently, CLB and DES modes are not available, and the flight crew must monitor constraints.
When the aircraft leaves the GO-AROUND phase, all predictions and modes become available again. During a GO-AROUND phase, the managed speed is Green Dot.

CAUTION	If ALT* engages, as the aircraft emerges from SRS mode, and an engine-out occurs more or less simultaneously, the aircraft may loose airspeed as it tries to capture altitude. There is no mode reversion in ALT*.



HEADING/TRACK PRESET FUNCTION IN GO-AROUND PHASE

The flight crew can use the heading/track preset, when LOC*, LOC, LAND, FINAL or GA is engaged.

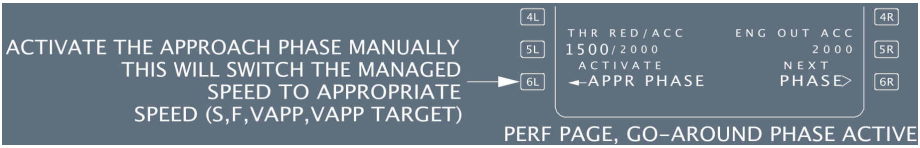
SET the appropriate heading, or track value, in the window of the FCU.
When necessary, PULL the HDG/TRK selection knob to engage the mode on the preset value.

MONITORING THE GO-AROUND

Applicable to: B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTG, B-HTH, B-HTI

Engage the GO-AROUND phase and GO-AROUND modes by setting the thrust levers to the TOGA position, if at least CONF1 is selected.
When the GO-AROUND phase is engaged, the previously-flown approach is automatically strung back into the flight plan at the end of the missed approach procedure.
In the GO-AROUND phase, the system makes no predictions. Consequently, CLB and DES modes are not available, and the flight crew must monitor constraints.

When the aircraft leaves the GO-AROUND phase, all predictions and modes become available again. During a GO-AROUND phase, the managed speed is Green Dot.



HEADING/TRACK PRESET FUNCTION IN GO-AROUND PHASE

The flight crew can use the heading/track preset, when LOC*, LOC, LAND, FINAL or GA is engaged.

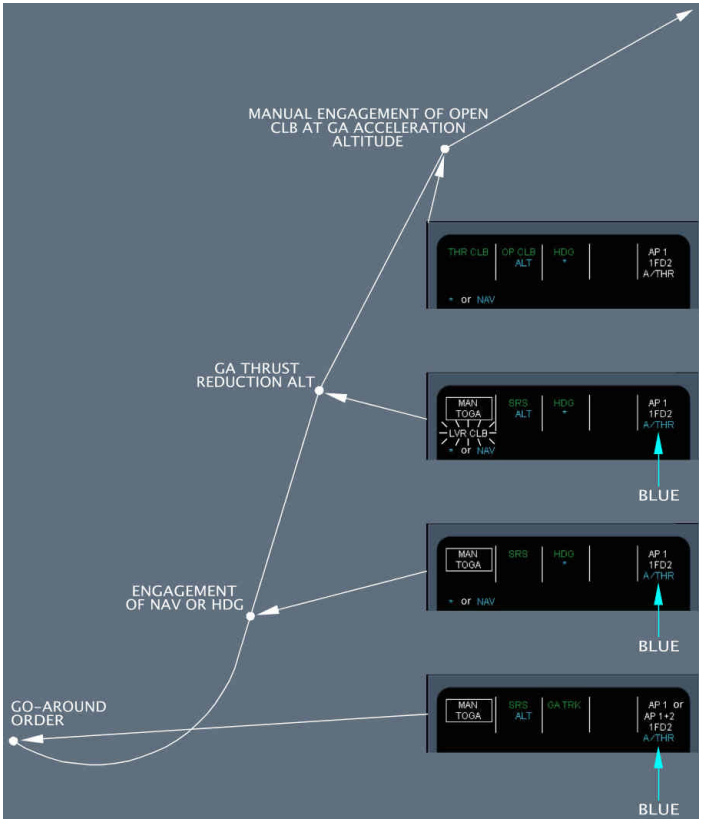
SET the appropriate heading, or track value, in the window of the FCU.
When necessary, PULL the HDG/TRK selection knob to engage the mode on the preset value.

GO-AROUND PROFILE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

- **WITH FD ON:**

  Apply SOP procedures

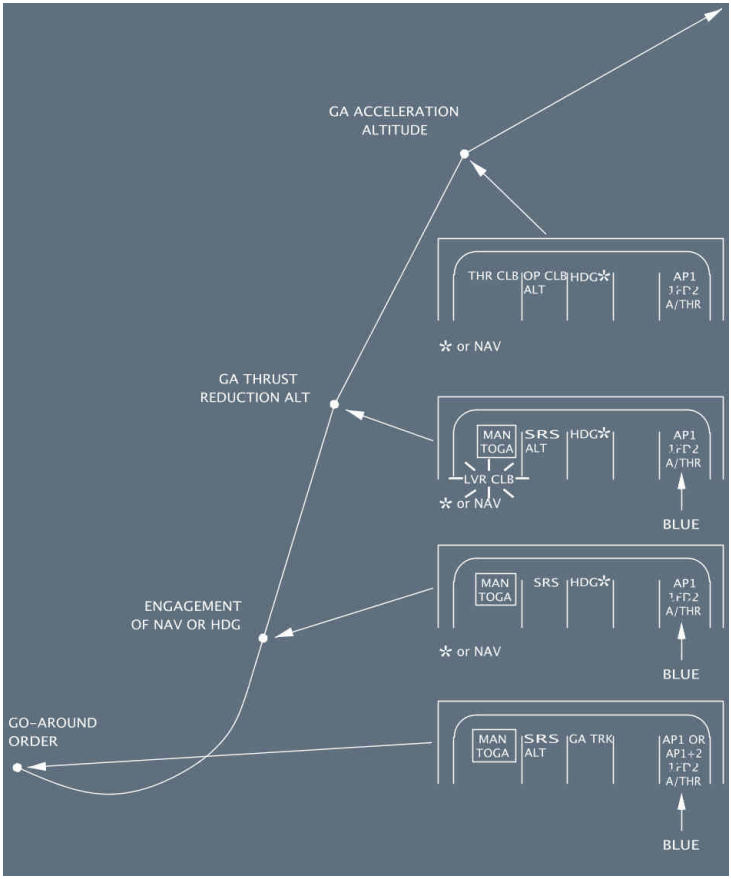


GO-AROUND PROFILE

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HTG, B-HTH, B-HTI

- **WITH FD ON:**

  Apply SOP procedures

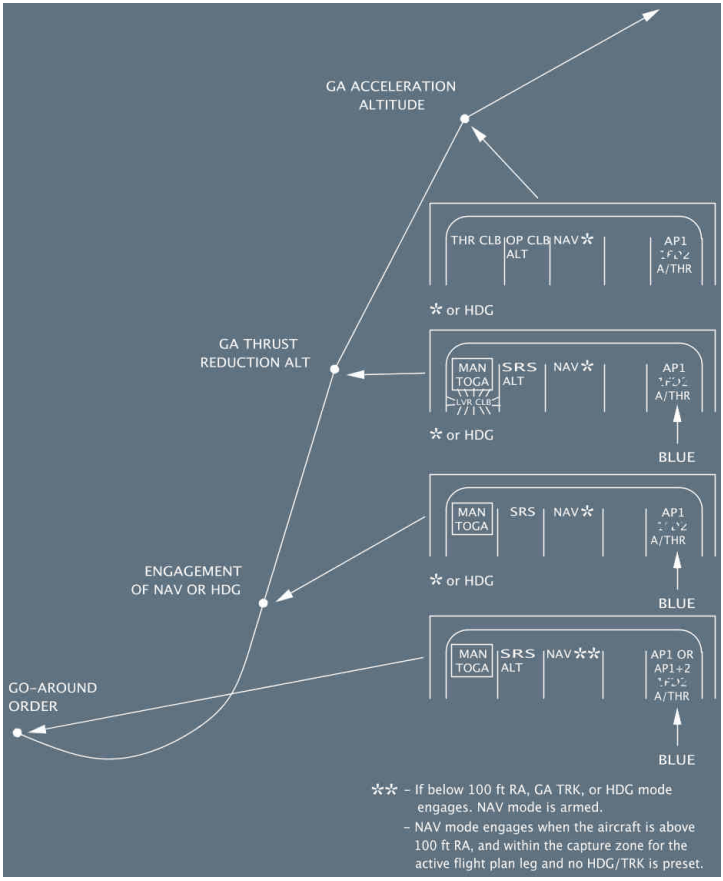


GO-AROUND PROFILE

Applicable to: B-HSP, B-HSQ, B-HSR

- **WITH FD ON:**

  Apply SOP procedures



MISSED APPROACH: TRY AGAIN

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

If the pilot intends to fly another approach to the destination:

- The flight plan has all the necessary data for the missed approach
- Green Dot is the target speed.

- **When cleared by the ATC to follow the missed approach procedure:**
  ENGAGE NAV mode, or
  TURN and PULL the HDG selector knob to set a heading
  HDG, or TRK, or NAV modes can only be engaged above 100 ft.

- **When entering the initial approach area:**
  Activate the approach phase on the MCDU's PERF GO AROUND page
  - **If the APPR phase is not activated:**
    - Managed approach speed will not be available
    - The system will not furnish predictions
    - MDA/MDH/DH displays will not appear on the PFD.

MISSED APPROACH: TRY AGAIN

Applicable to: B-HSQ, B-HSR

If the pilot intends to fly another approach to the destination:
- The flight plan has all the necessary data for the missed approach
- Green Dot is the target speed.

- **When cleared by the ATC to follow the missed approach procedure:**
  ENGAGE NAV mode, or
  TURN and PULL the HDG selector knob to set a heading
  HDG, or TRK, or NAV modes can only be engaged above 100 ft.

- **When entering the initial approach area:**
  Activate the approach phase on the MCDU's PERF GO AROUND page
  - **If the APPR phase is not activated:**
    - Managed approach speed will not be available
    - The system will not furnish predictions
    - BARO/RADIO minima displays will not appear on the PFD.

MISSED APPROACH: DIVERT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- **If the crew decides to divert to the alternate:**
  ENABLE ALTN, preferably at the TO waypoint.

- **When cleared to a waypoint:**
  PERFORM a DIRECT TO.

The system automatically reverts to CLB phase, and modifies the target speed from Green Dot to initial speed.

The system automatically sets the CRZ FL to the defaulted alternate CRZ FL (FL 220 or 310), and retains the previous cost index.

The pilot may adjust these as necessary.

Note: Diversion may also be initiated by entering a NEW DEST in the LAT REV page at the TO waypoint, or by using the secondary F-PLN, if prepared. Refer to DSC-22_20-60-30 General.

MISSED APPROACH: DIVERT

Applicable to: B-HSQ, B-HSR

- **If the crew decides to divert to the alternate:**

  ENABLE ALTN, preferably at the TO waypoint.

- **When cleared to a waypoint:**

  PERFORM a DIRECT TO.

  The system automatically reverts to CLB phase, and modifies the target speed from Green Dot to initial speed.

  The system automatically sets the CRZ FL to the defaulted alternate CRZ FL (FL 220 or 310), The Cost Index is set to 0.0 and the message USING COST INDEX 0 is triggered.

  The pilot may adjust these as necessary.

  Note: Diversion may also be initiated by entering a NEW DEST in the LAT REV page at the TO waypoint, or by using the secondary F-PLN, if prepared. Refer to DSC-22_20-60-30 General.

GENERAL

Applicable to: ALL

Flight without cabin pressurization can result of:
- Dispatch under MEL
- Departure following a structural damage
- Depressurization in flight

The flight crew must decide the flight level and the airspeed depending on:
- The cause of the depressurization
- The distance to fly
- The topographic conditions
- The meteorological conditions, and
- The passengers on board the aircraft.

Revenue flight is permitted without cabin pressurization, provided that the oxygen requirements below are achieved.

FUEL TRANSFER

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Automatic fuel transfer from the ACT(s) to the center tank will not occur during flight without cabin pressurization. At the time when the automatic fuel transfer from the ACT(s) should start, the “ACT XFR FAULT” ECAM caution will be triggered to indicate that the automatic transfer will not occur. The flight crew should follow the ECAM caution to perform a manual fuel transfer.

OXYGEN REQUIREMENTS

Applicable to: ALL

CREW MEMBERS

See FAR 121.329 or JAR-OPS 1.770

PASSENGERS

For flight at cabin pressure altitudes above 10 000 ft, up to and including 14 000 ft, there must be enough oxygen to supply 10 % of the passengers for the flight at those altitudes that lasts more than 30 min.
For flight at cabin pressure altitudes above 14 000 ft, up to and including 15 000 ft, there must be enough oxygen for 30 % of the passengers.
For flight at cabin pressure altitudes above 15 000 ft, there must be enough oxygen for all passengers.

FLIGHT PLANNING AND EXECUTION

Applicable to: ALL

ALTITUDE

Flight route planning should consider the above-stated restriction in cabin altitude. If cabin altitude exceeds 9 550 ±350 ft, the EXCESS CAB ALT warning on the ECAM will be activated. When above 14 000 ft, the passenger oxygen masks will drop automatically. Therefore, the recommended maximum altitude for prolonged flight is FL 100. The minimum altitude should be selected by respecting :

- The Minimum Safe Altitude (MSA),
- Turbulence, which is uncomfortable for passengers and,
- Low Outside Air Temperature (OAT), which can be uncomfortable for passengers when the cabin is ventilated by ram air only.

AIRSPEED

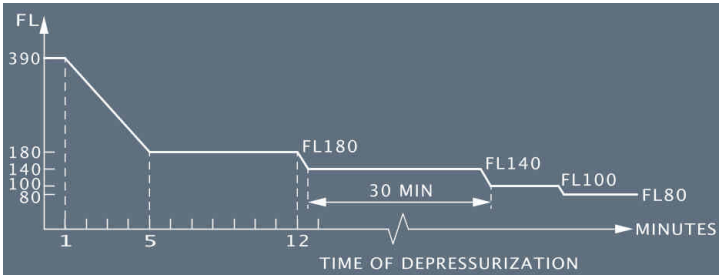
If decompression is due to structural damage, consider airspeed reduction. Use slats and flaps, as necessary, to establish low speed conditions. In addition, turbulent conditions are uncomfortable for passengers, and gust response should be minimized by reducing airspeed.

CLIMB AND DESCENT RATE

Takeoff must be performed normally, and the rate of climb must be limited to about 500 ft/min, to ease the pressure change felt by passengers and crew.
Likewise, the rate of descent must be limited to about 1 000 ft/min, except for the final approach which must be performed normally. Notify the ATC of any performance deficiency by a remark in the flight plan.

EMERGENCY DESCENT IN CASE OF RAPID DEPRESSURIZATION

In the event of depressurization, oxygen is supplied to passengers through an individual mask. The capacity of the units is such that the aircraft must descend and remain below the following profile.



SYSTEMS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FAILURE OCCURRING IN FLIGHT

Apply the abnormal and emergency procedures required by ECAM.

FAILURE PRESENT AT DISPATCH

- **If flight with both packs inoperative**

  PACK 1 and 2.....OFF
  RAM AIR..... ON

  Note: *If the "AVIONICS SMOKE" procedure has to be applied, the following flight time limitations have to be considered to protect the avionic equipment :*
  At ISA +40 : 0.5 h
  At ISA +30 : 1.5 h
  At ISA +20 : 4 h
  At ISA +10 and below : No limitation.

  Between FL 80 and FL 150, oxygen must be provided for 2 % of the passengers. This is provided by the portable oxygen system. When it is no longer available, descend to FL 80. For performance at FL 80/250 kt : Use data for FL 100/LRC (*Refer to PER-CRZ-CRT-30 LONG RANGE CRUISE - ISA*) and increase fuel consumption by 6 %.

- **If both CAB PRESS systems are inoperative, or if there is structural damage :**

  PACK 1 and 2.....ON
  MODE SEL..... MAN
  V/S CTL..... AS RQRD

  Use V/S CTL pb to set the outflow valve opening to 50 %.

  OUTFLOW VALVE HALF OPEN.....CHECK

  The outflow valve opening is limited to 50 %, to prevent the cabin air suction effect.

MAX FL.....100 or MSA

TAKEOFF

Limit the aircraft's rate of climb to about 500 ft/min.

CLIMB

Note: The EXCESS CAB ALT warning may occur.
Use the ECAM CLR pb to clear the warning.

DESCENT

Limit the aircraft's rate of descent to about 1 000 ft/min. Perform the final approach normally.

SYSTEMS

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

FAILURE OCCURRING IN FLIGHT

Apply the abnormal and emergency procedures required by ECAM.

FAILURE PRESENT AT DISPATCH

- **If flight with both packs inoperative:**

PACK 1 and 2.....OFF
RAM AIR.....ON

Note: If the "AVIONICS SMOKE" procedure has to be applied, the following flight time limitations have to be considered to protect the avionic equipment :
At ISA +40 : 0.5 h
At ISA +30 : 1.5 h
At ISA +20 : 4 h
At ISA +10 and below : No limitation.

MAX FL.....100 or MSA

Between FL 80 and FL 150, oxygen must be provided for 2 % of the passengers. This is provided by the portable oxygen system. When it is no longer available, descend to FL 80. For performance at FL 80/250 kt : Use data for FL 100/LRC (Refer to PER-CRZ-CRT-30 LONG RANGE CRUISE - ISA) and increase fuel consumption by 6 %.

- **If both CAB PRESS systems are inoperative, or if there is structural damage:**

TEST OF THE MANUAL OPERATION OF THE OUTFLOW VALVE ON GROUND:

PACK 1 pb-sw and PACK 2 pb-sw.....OFF
OUTFLOW VALVE FULLY OPEN.....CHECK

Check that the outflow valve is fully open on the CAB PRESS SD page

RPCU C/B (X23 ON 122VU)..... PULL
MODE SEL pb ..... MAN
MAN V/S CTL..... DN
Check that the outflow valve is fully open on the CAB PRESS SD page
MAN V/S CTL..... UP
Check that the outflow valve is fully open on the CAB PRESS SD page
MODE SEL pb ..... AUTO
RPCU C/B (X23 ON 122VU)..... PUSH
PACK 1 pb-sw and PACK 2 pb-sw..... ON
MAX FL.....100 or MSA

Between FL 80 and FL 150, oxygen must be provided for 2 % of the passengers. This is provided by the portable oxygen system. When it is no longer available, descend to FL 80. For performance at FL 80/250 kt : Use data for FL 100/LRC (Refer to PER-CRZ-CRT-30 LONG RANGE CRUISE - ISA) and increase fuel consumption by 6 %.

TAKEOFF

Limit the aircraft's rate of climb to about 500 ft/min.

- **If both CAB PRESS systems one inoperative, or if there is structural damage:**
  - **WHEN IN CLEAN CONFIGURATION:**

MODE SEL pb ..... MAN
V/S CTL sw .....AS RQRD
Use V/S CTL pb to set the outflow valve opening to 50 %.
OUTFLOW VALVE HALF OPEN..... CHECK
The outflow valve opening is limited to 50 %, to prevent the cabin air suction effect.

CLIMB

Note: The EXCESS CAB ALT warning may occur.
Use the ECAM CLR pb to clear the warning.

DESCENT

Limit the aircraft's rate of descent to about 1 000 ft/min. Perform the final approach normally.

PERFORMANCE DATA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following table enables the fuel consumption and the time needed from takeoff to landing to be determined in case of flight without cabin pressurization.

The table is established for :
- Takeoff
- Climb from 1 500 ft at 250 kt
- Long range cruise speed at FL 100
- Descent to 1 500 ft at 250 kt
- Approach and landing : IMC procedure 120 kg or 260 lb (6 min)
- ISA temperature
- CG = 25 %
- Normal air conditioning
- Anti ice OFF

The table (*Refer to PRO-SPO-20 Ground Distance/Air Distance Conversion*) gives the conversion from ground distance to air distance

Note: *For each degree Celcius above ISA temperature apply a correction of 0.01 (kg/°C/NM) or 0.022 (lb/°C/NM).*

PERFORMANCE DATA

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

GENERAL

Applicable to: ALL

This Chapter applies to dispatch with landing gear down. However, the limitations and inflight performance also apply in case of an inflight landing gear retraction failure.
Revenue flight is permitted, with the landing gear down and the gear doors closed, in the conditions stated below.

Intentionally left blank

LIMITATIONS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

- Do not fly into expected icing conditions.
- Ditching with the landing gear down has not been demonstrated.
- Disregard FM fuel predictions. Other predictions should also be disregarded (altitude, speed and time), except time predictions at waypoints when in cruise.
- Do not use managed speed (except in approach) and CLB and DES autopilot modes.
- ALTITUDE ALERT is not available.
- The APU must run during the whole flight. APU GEN must be available.
- Select TCAS "TA only" mode.

LIMITATIONS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- Do not fly into expected icing conditions.
- Ditching with the landing gear down has not been demonstrated.
- Disregard FM fuel predictions. Other predictions should also be disregarded (altitude, speed and time), except time predictions at waypoints when in cruise.
- Do not use managed speed (except in approach) and CLB and DES autopilot modes.
- ALTITUDE ALERT is not available.
- Select TCAS "TA only" mode.

Intentionally left blank

PREFLIGHT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

- VMO/MMO with the landing gear down is 235 kt/M .60. In the avionics compartment, on 188 VU, the VMO-MMO switch must be set to the "L/G DOWN" position.
- The check of ELAC 2 standby power supply availability, in case of BLUE hydraulic pressure loss must be performed during cockpit preparation, if not already done by maintenance. This ensures that, if the crew forgets to reset the LGCIU 1C/B during approach in EMER ELEC configuration, ELAC 2 will be supplied by Battery 2, should the RAT stall during flare.

YELLOW ELEC PUMP.....ON
PTU.....Check AUTO
BLUE PUMP OVRD.....ON
LGCIU 1 C/B (C09).....PULL
LGCIU/SYS 1/GND SPLY (Q34 if installed).....PULL

This simulates the L/G in retracted position.
Check that the "ELAC 2" indication is green on the ECAM F/CTL page.

ELAC 2/NORM/SPLY (R20 on rear panel).....PULL

Check that the ELAC 2 indication changes to amber.

THS ACTR/MOT 1 (Q16 on rear panel).....PULL

This simulates the EMER ELEC configuration.
Check that the ELAC 2 indication is again green for about 30 s, and that it then changes to amber.

BLUE ELEC PUMP OVRD.....OFF

This simulates a RAT stall in EMER ELEC configuration.

- *BLUE hydraulic system is depressurized.*
- *Check ELAC 2 indication changes to green.*

C/Bs.....RESET

Reset	*LGCIU 1 C/B :*	*C09,*
		Q34 (if installed)
	ELAC 2 C/B :	*R20*
THS ACTR/MOT 1 C/B :		*Q16*

YELLOW ELEC PUMP.....OFF

PREFLIGHT

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

VMO/MMO with the landing gear down is 235 kt/M .60. In the avionics compartment, on 188 VU, the VMO-MMO switch must be set to the "L/G DOWN" position.

NORMAL PROCEDURES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

- **After engine start :**

  APU.....KEEP ON

  Keep the APU running for the duration of the flight.

ABN AND EMER PROCEDURES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

FLIGHT CONTROLS

Failure cases, which would normally lead to ALTN law, will degrade F/CTL laws down to DIRECT law, if the landing gear is extended.

ALL GENERATOR FAILURE

- **The aircraft is supplied by batteries only.**

  To recover the emergency generator

  LGCIU 1 C/B (C09).....PULL
  EMER ELEC PWR.....MAN ON

CAUTION	*Minimum speed is 180 kt instead of 140 kt given by ECAM.*

- **During deceleration (before reaching 200 kt) :**

  LGCIU 1 C/B (C09).....PUSH

  Emergency generator will be deactivated.
  Minimum speed is 140 kt.

ABN AND EMER PROCEDURES (CONT'D)

- **In case of go-around, when above 200 kt**

  LGCIU 1 C/B (C09).....PULL
  EMER ELEC PWR.....MAN ON

FAILURE OF BOTH ENGINES

When both engines are failed, to ease the handling of all the different ECAM procedures resulting from this all engine flame out situation, it is recommended to use the ENG DUAL FAILURE QRH paper procedure, and if time permits, to clear the ECAM.
Follow all the steps of the QRH paper procedure, except those that are modified by the procedure below :

- **If APU is available** : perform an assisted relight when below FL 200.
- **If APU is not available**
  - Do not attempt to start the APU (APU start is inhibited in this configuration)
  - Windmilling relight can be performed, as long as the speed is above 260 kt (corresponding N2 above 18 %). In this case, increase aircraft speed and disregard VMO warning.
  - Flight controls are in direct laws. Use manual pitch trim as necessary (not indicated on PFD if APU GEN not available).
  - Do not use LGCIU 1 C/B.
- **In approach, above 200 kt :**
  FLAPS 1 ..... SELECT
  Set FLAPS 1 above 200 kt to avoid RAT stall.
- **For landing :**
  FOR LDG ..... USE FLAPS 1
  APPR SPD ..... VREF + 25 kt / 150 kt
  The approach speed is the maximum between Vref + 25 kt / 150 kt

AVIONICS SMOKE

If smoke persists more than 5 min, the LGCIU 1 C/B (C09 on 49 VU) must be pulled before RAT extension. Minimum speed is 180 kt (instead of 140 kt given by ECAM).
During approach :

GEN 2 ..... ON
EMER ELEC GEN 1 LINE ..... ON
LGCIU 1 C/B (C09 on 49 VU) ..... PUSH

ABN AND EMER PROCEDURES

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FLIGHT CONTROLS

Failure cases, which would normally lead to ALTN law, will degrade F/CTL laws down to DIRECT law, if the landing gear is extended.

FAILURE OF BOTH ENGINES

When both engines are failed, to ease the handling of all the different ECAM procedures resulting from this all engine flame out situation, it is recommended to use the ENG DUAL FAILURE QRH paper procedure, and if time permits, to clear the ECAM.
Follow all the steps of the QRH paper procedure, except those that are modified by the procedure below :

■ **If APU is not available**

- Attempt an APU start
- . If APU start is unsuccessful, a windmilling relight can be performed, as long as the speed is above 260 kt (corresponding N2 above 18 %). In this case, increase the aircraft speed and disregard VMO warning.

■ **If APU is available** : perform an assisted relight, when below FL 200.

- Flight controls are in direct laws. Use manual pitch trim as necessary (not indicated on PFD if APU GEN not available).

GENERAL

Applicable to: ALL

Consider the increase in drag to determine the takeoff weight and fuel consumption.
CONF 1 + F is the recommended takeoff configuration.

Note: *Takeoff with tail wind is not recommended.*

Penalties on takeoff performance affect second segment gradient condition, final takeoff condition and en-route conditions. The takeoff weight to be retained is the most limiting of these three conditions.

SECOND SEGMENT GRADIENT CONDITION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The RTOW charts or the quick reference tables give the basic information for normal takeoff. To simplify, a constant weight reduction is applied whatever the limitation. This weight reduction covers the most critical case presented for flying over an obstacle.

Takeoff configuration	1 + F	2	3
Weight reduction	21 %	19 %	17 %

METHOD

Use the RTOW chart or the quick-reference tables to define the maximum takeoff weight for the conditions on the airport (temperature, pressure, wind, runway...), then apply the above weight reduction.

SECOND SEGMENT GRADIENT CONDITION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The RTOW charts or the quick reference tables give the basic information for normal takeoff. To simplify, a constant weight reduction is applied whatever the limitation. This weight reduction covers the most critical case presented for flying over an obstacle.

Takeoff configuration	1 + F	2	3
Weight reduction	22 %	18 %	18 %

METHOD

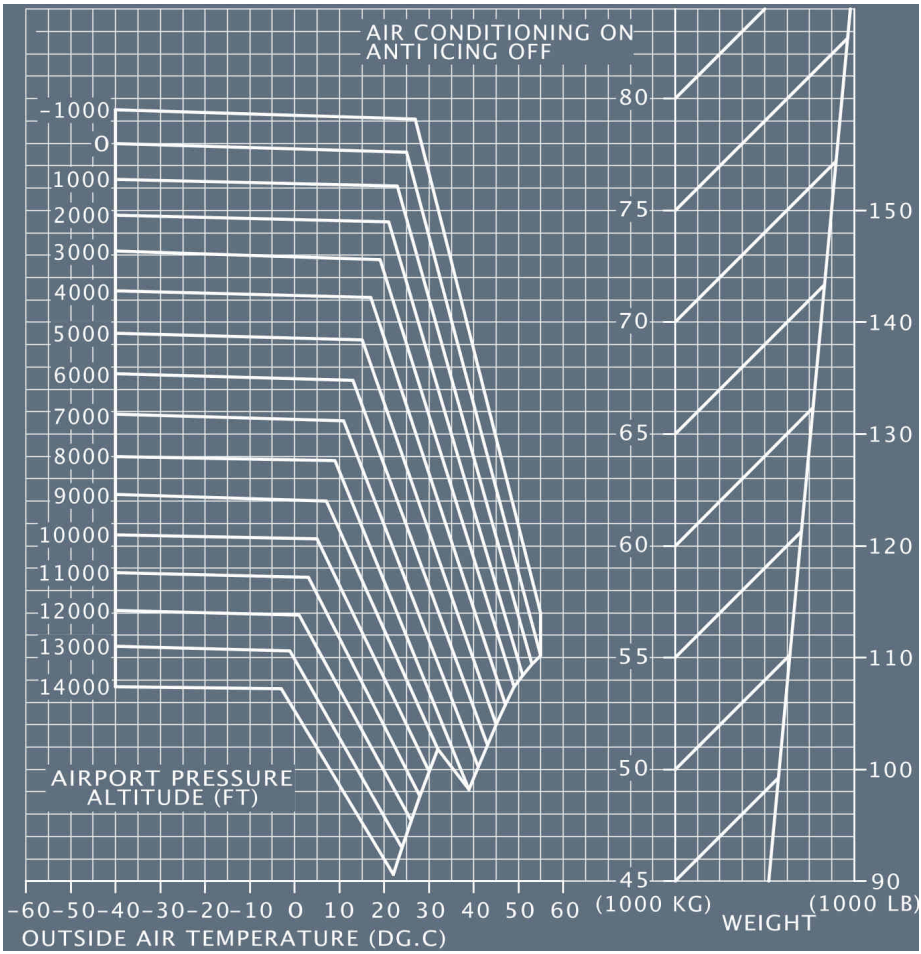
Use the RTOW chart or the quick-reference tables to define the maximum takeoff weight for the conditions on the airport (temperature, pressure, wind, runway...), then apply the above weight reduction.

FINAL TAKEOFF CONDITION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The final takeoff speed is VLS.

Use the graph below to determine the maximum takeoff weight associated with the final takeoff condition.



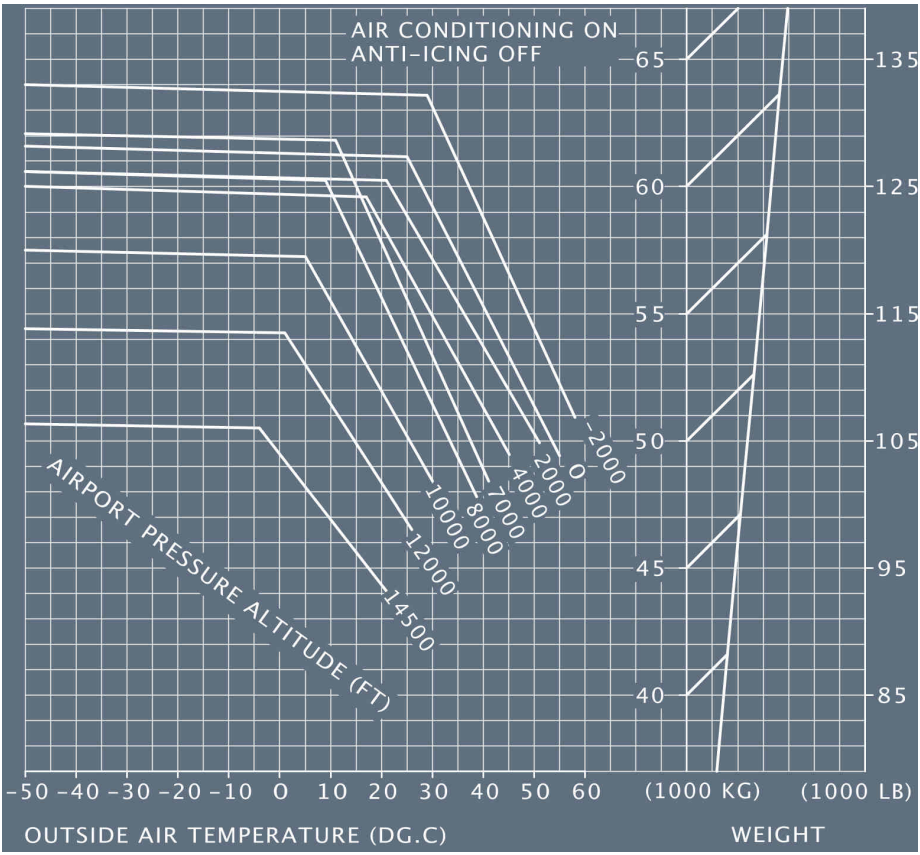
FINAL TAKEOFF CONDITION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The final takeoff speed is VLS.

Use the graph below to determine the maximum takeoff weight associated with the final takeoff condition. This graph is established for 25 % CG location.

In case of forward CG the weight must be decreased by 600 kg (1 350 lb).



EN ROUTE CONDITION

Applicable to: ALL

Retain the lowest weight according to the most limiting condition (second segment or final takeoff). Use the en route net flight path (*Refer to PRO-SPO-25-40 En Route Net Flight Plan*) to check that in case of engine failure the aircraft can clear the terrain on the route by 1 000 ft (climbing) or 2 000 ft (descending). If necessary, reduce the takeoff weight. Read the speeds corresponding to this weight in the RTOW chart or in the quick reference tables.

GO AROUND PERFORMANCE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Refer to PER-GOA-GEN GENERAL for go-around requirements.
Further decrease the basic limiting weight by 15 %.

GO AROUND PERFORMANCE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Refer to PER-GOA-GEN GENERAL for go-around requirements.
Further decrease the basic limiting weight by 12 %.

FLIGHT PLANNING

Applicable to: ALL

Note: *The performance tables are established at ISA. For each degree Celsius above ISA temperature and per NM of air distance apply a fuel correction of 0.05 kg/°C/NM (0.11 lb/°C/NM).*

CLIMB

Climb at 230 kt/M 0.50 with both engines at maximum climb thrust. The table (*Refer to PRO-SPO-25-40 Climb*) gives the time, distance and fuel consumption according to takeoff weight.

CRUISE/DESCENT

The recommended cruise/descent speed is 230 kt/M 0.50.
The ceiling on one engine may be a limiting factor, and the choice of the route should reflect this concern.

ENGINE FAILURE

In case of engine failure, the airplane will drift down to the ceiling shown (*Refer to PRO-SPO-25-40 Gross Ceilings at Long Range and Green Dot Speeds - One Engine Out*).
The thrust for drift down will be Maximum Continuous.

The drift down speed is equal to green dot speed.

HOLDING

For the holding parameters with slats out, this configuration being the least penalizing for holding:
Refer to PRO-SPO-25-40 Race Track Holding Pattern.

CLIMB

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

CLIMB 230KT/M.50 - ALL ENGINES - L/G DOWN

INTRODUCTION

Applicable to: ALL

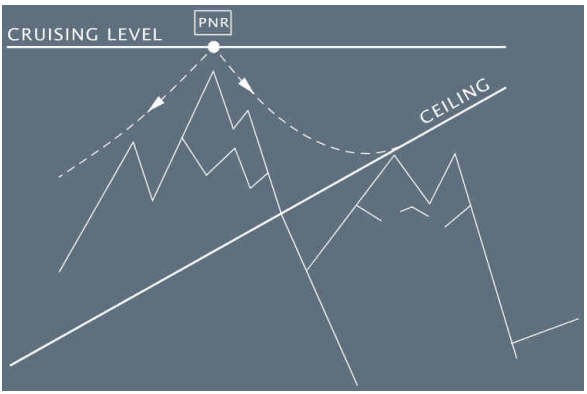
Two failures must be taken into consideration for en route obstacle clearance over mountainous area :

- Engine failure that forces a descent to a lower cruise level
- Depressurization which, due to the passenger oxygen system, requires a descent to 10 000 ft before supplementary oxygen is exhausted.

ENGINE FAILURE

Applicable to: ALL

If the standard strategy does not allow the aircraft to clear obstacles, the pilot must use a drift down procedure. If an engine failure occurs at any point on the route, the net flight path must clear the obstacles on the drift-down part by 2 000 ft and on the climb part by 1 000 ft.
If the aircraft cannot clear the en route obstacles, a point of no return (PNR) must be determined.



If an engine failure occurs after the PNR, the aircraft must drift down on course. If the failure occurs before the PNR, the aircraft must turn back.
For en route net flight paths, refer to the Aircraft Flight Manual.

DEPRESSURIZATION

Applicable to: ALL

In case of depressurization, the passengers receive oxygen through individual modules. An emergency descent in accordance with a certain profile has to be performed:*Refer to PRO-SPO-20 General*

CONCLUSION

Applicable to: ALL

A detailed study of each route over mountainous area must show that single-engine net flight path and passenger oxygen system performance allow the aircraft to clear the obstacles by 1 000 ft in climb and by 2 000 ft in cruise or descent.

If the aircraft in these circumstances cannot clear the obstacles on the route, a PNR must be determined and diversion procedures must be established.

GENERAL

Applicable to: ALL

The system design and the reliability of the engine installation of this airplane comply with the criteria for Extended Twin Operations (ETOPS) flights set forth in AMC 20-6 rev. 2 (EASA) or FAR 25.1535 (FAA), when the aircraft is configured, maintained and operated in accordance with the Airbus CMP (Configuration, Maintenance and Procedure) document.

This statement of ability does not constitute an approval to conduct Extended-Range Operations.

The ETOPS EXTENDED OPERATIONS Chapter of the AFM APPENDICES AND SUPPLEMENTS Section refers to the approved Standard for Extended-Range Operations and the applicable limitations, procedures and performance references.

The operator is responsible for showing that he is complying with the regulation of his nation and for obtaining operational approval from his national authorities. The operator may amend this chapter, as needed.

The airplane must be configured in accordance with the Airbus Standard for Extended-Range Operations. However, the authorities may under certain conditions allow the operator to conduct ETOPS flights with limited maximum diversion time (for example, 75 min diversion time in a benign area of operation) without showing full compliance with these standards.

Intentionally left blank

DEFINITIONS

Applicable to: ALL

For the purpose of EU-OPS 1-245 and FAR 121-161, Extended-Range Operations are those intended to be conducted over a route that contains a point beyond 60 min from an adequate airport at the selected one-engine-inoperative speed in still air and ISA (or prevailing delta ISA) conditions.
An adequate airport is an airport which satisfies the aircraft performance requirements applicable at the expected landing weight, and sufficiently equipped to be safely used. In particular, at the anticipated time of use, it should be available and equipped with the necessary services, including ATC, weather information, navaids and emergency services.
An ETOPS (en-route) alternate airport is a confirmed adequate airport which satisfies the dispatch weather minima requirements for ceiling and visibility within the required validity period.

AREA OF OPERATION

Applicable to: ALL

The ETOPS area of operations is the airspace within which the distance to an ETOPS adequate airport is less than the ETOPS Max Diversion distance.
The ETOPS maximum diversion distance from an adequate airport must be determined for ISA (or prevailing delta ISA) and no-wind conditions, taking into account aircraft performance with one engine inoperative and the remaining engine operating at MCT.
To determine the ETOPS maximum diversion distance from an adequate airport, the operator must define a One Engine Inoperative diversion speed for performance computation.

The same approved one-engine-inoperative diversion speed (*Refer to PER-OEI-GEN-05 STRATEGY*) must be considered for :
- Establishing the area of operation,
- Calculating the single-engine fuel planning,
- Conducting the diversion in case of engine failure (conditions permitting).

The operator has to define an aircraft weight at diversion that is considered for the ETOPS Maximum Diversion Distance calculation. This aircraft weight can be taken as a representative but conservative value of the aircraft gross weight at the critical point of the route or at the various critical points of all the routes included in a given sector.
The approved one-engine-inoperative descent and cruise speed must be chosen so that the associated net flight path clears the en-route obstacles with the regulatory margin. However, a speed other than the approved one-engine-inoperative speed may be used as the basis for obstacle clearance as long as the fuel required with that speed is covered by the critical fuel scenario.
Refer to PER-OEI-GEN-15 PROCEDURE for these two one-engine-inoperative speeds.

When the one-engine-inoperative diversion speed is chosen, the maximum distance from a diversion airport, can be directly determined for different maximum diversion times, with the help of the tables provided in this section. The area of possible ETOPS operation can then be drawn on plotting charts.
Another way to determine the maximum distance to a diversion airport is to read the one-engine-inoperative cruise TAS (for the reference gross weight and at the FL for best TAS) in the cruise tables (*Refer to PER-OEI-GEN-05 STRATEGY*) taking into consideration the appropriate speed strategy and the minimum altitude for clearing possible obstacles. The maximum distance the aircraft can travel to a diversion airport is this one-engine-inoperative-TAS multiplied by the maximum allowed diversion time granted to the operator.
Operators whose authorities require that an approved one-engine-inoperative speed be published in the Flight Manual must use this approved speed.

MMEL

Applicable to: ALL

The MMEL has been approved taking into consideration the duration of the average ETOPS flight and the maximum diversion time granted to the airframe/engine combination.
The MMEL published by Airbus and approved by the French DGAC can be used to establish the airline MEL, which must be approved by the operator's national authorities.
This MEL will probably be adapted to the airline network, environment and organization.

Other determining parameters will be :

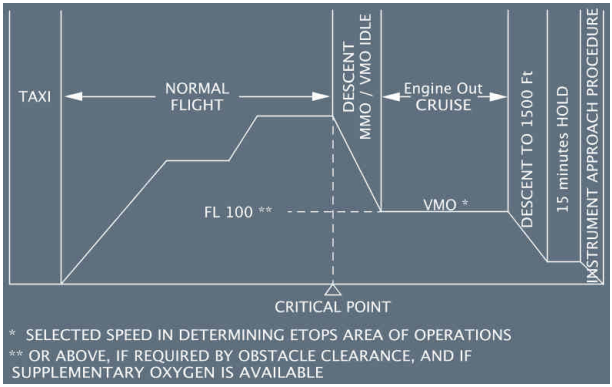
- The maximum and the average diversion times on the route.
- The equipment of the enroute alternates.
- The navigation and communication facilities.
- The average meteorological conditions.

ETOPS FUEL SCENARIOS

Applicable to: ALL

According to EASA AMC 20-6 rev 2 and FAA 121.646 for establishing the ETOPS critical fuel reserves, the operator must consider three diversion scenarios:

- Pressurization Failure + Engine Failure



- Pressurization Failure
  Same Flight Profile as above, but all engines operating and Diversion Cruise Speed* set to LRC.

- Engine Failure
  Same Flight Profile as above, but standard descent speed and Diversion Cruise at the FL** appropriate to gross engine out ceiling at the selected ETOPS diversion speed.
- FAA Fuel Requirements
  For the first two scenarios, involving depressurization, the required block fuel must be calculated in accordance with the operator's ETOPS fuel policy and using the regulatory ETOPS critical fuel reserves *Refer to PRO-SPO-40-30 ETOPS Critical Fuel Reserves*.
  Depending on the approved one-engine-inoperative speed selected for the single-engine diversion strategy, either of these two scenarios may result in the higher fuel requirement.
  The scenario resulting in the higher fuel requirement is called the ETOPS critical fuel scenario, and the associated minimum block fuel requirement is the ETOPS critical fuel plan.
  Note that, it is not necessary to calculate the 3rd scenario (engine failure), as this scenario is never critical, due to the higher diversion flight level.

ETOPS CRITICAL FUEL RESERVES

Applicable to: ALL

For the computation of the ETOPS critical fuel reserves and of the complete ETOPS critical fuel planning according to EASA AMC 20-6 rev 2 and FAR 121.646, the diversion fuel must include the following fuel provisions:

- Fuel burn-off from the critical point to the end of descent at the alternate airport
- Fuel for 15 min of holding at 1 500 ft and green dot speed at the alternate
- Fuel for an instrument approach and landing
- Fuel to account for errors in wind forecasting (5 % wind speed factor on actual forecast wind speeds or 5 % fuel if actual forecast wind speeds are not used)
- Fuel to account for aircraft deterioration (use a demonstrated performance factor or 5 %)
- Fuel to account for any Configuration Deviation List (CDL) or MEL item
- Fuel to account for Icing Effects (if forecast) for the critical mission
- Fuel to account for APU use (only for the one-engine-inoperative scenario, if APU is operative)

WIND ERRORS

A 5 % wind speed factor (i.e. an increment to headwind or a decrement to tailwind) on the actual forecast wind should be used to account for potential errors. However if the operator is not using the actual forecast wind based on a wind model acceptable to the certification authorities then 5 % of the fuel for the critical scenario is required as a reserve fuel.

ICING

The most critical scenario must be compensated for the greater of:

A. The effect of airframe icing during 10 % of the time during which icing is forecast, including ice accumulation on unprotected surfaces, and the fuel used by engine and wing anti-ice during this period.

B. Fuel for engine and wing anti-ice for the entire time during which icing is forecast.

Note: The ETOPS icing fuel reserve is always limited by (B)

Unless a reliable icing forecast is available, icing may be presumed to occur when the Total Air Temperature (TAT) is less than +10 °C, or if the outside air temperature is between 0 °C and -20 °C with a relative humidity of 55 % or more.

APU

Fuel consumption of 80 kg/h / or 176 lb/h (APU GEN ON, APU BLEED OFF).
In view of our experience, Airbus recommends that the operator includes a contingency fuel provision from departure to the Critical Point (CP), when computing the ETOPS critical fuel planning.

ETOPS FUEL REQUIREMENTS

Applicable to: ALL

The operator must compare the entire ETOPS critical fuel planning for the ETOPS critical fuel scenario with the standard fuel planning computed in accordance with the company fuel policy and applicable operational requirements. The higher of the two fuel requirements must be considered as the minimum required block fuel for the flight.

WEATHER MINIMA

Applicable to: ALL

Weather forecasts for en-route alternates must meet the operator's applicable weather minimum requirements.
This paragraph provides the applicable minima required by EASA (EU-OPS 1/ AMC 20-6 rev. 2) and FAA (AC120-42B).

A. EASA DISPATCH WEATHER MINIMA (EU-OPS 1/ AMC 20-6 REV. 2)

An airplane cannot be dispatched unless the meteorological forecasts at ETOPS en-route alternate airports meet the weather minima listed here for a period commencing at the earliest potential time of landing and ending one hour after the latest expected time of landing:

Approach Type	Min ETOPS Ceiling	Min ETOPS Visibility
Precision approach	DH/DA +200 ft	Authorised visibility +800 m
Non-Precision or Circling approach	MDH/MDA +400 ft	Authorised visibility +1 500 m
CAT II/CAT III approach	Specific approval required	Specific approval required

B. FAA DISPATCH WEATHER MINIMA (AC 120-42B)

An airplane cannot be dispatched unless the meteorological forecasts at ETOPS en-route alternate airports meet the weather minima listed here for a period commencing at the earliest potential time of landing and ending at the latest expected time of landing:

Approach Type	Min ETOPS Ceiling	Min ETOPS Visibility
Two or more instrument approaches	Higher of the two (M)DH/DA +200 ft	Higher of the two authorised visibility +800 m
Single Precision approach or Non-Precision approach or Circling approach	(M)DH/DA +400 ft	Authorised visibility +1 600 m
CAT II approach	300 ft	1 200 m or RVR 1 200 m
CAT III approach	200 ft	800 m or RVR 550 m

DIVERSION DECISION MAKING

Applicable to: ALL

The technical criteria governing a re-routing or diversion decision can be classified into four categories, as follows :

- Loss of MNPS capability, before entering the MNPS area (as applicable).
- Weather minima at diversion airport(s) going below the company/crew en-route minima, before reaching the ETOPS Entry Point, or diversion airport(s) becoming unsuitable for any reason.
- Failure cases requiring a diversion to the nearest airport (cases leading to a LAND ASAP message on the ECAM and/or in the QRH).
- Failure cases resulting in increased fuel consumption, exceeding the available fuel reserves.

Comments and Recommendations

- Electrical generation

  If one IDG fails, a diversion is required in case of :
  - Blue hydraulic circuit low level, low air pressure or overheat, or
  - APU no start, or
  - APU or APU generator inoperative, or
  - Second IDG failure.

- Fuel system
  Some failure cases may lead to fuel gravity feeding which implies flight at lower altitude or to some fuel being unusable. The flight crew's evaluation of the actual situation and the fuel remaining may lead to the decision that a diversion is required.
- Hydraulic system :

  If low level, low air pressure or overheat on blue hydraulic circuit, a diversion is required in case of :
  - One IDG failure, or
  - APU no start, or
  - APU/APU GEN failure.

- APU :

  If APU/APU GEN fails, a diversion is required in case of :
  - Blue hydraulic circuit low level, low air pressure or overheat, or
  - One IDG failure.

DIVERSION PERFORMANCE DATA

Applicable to: ALL

Chapter PER-OEI-GEN contains three single engine descent and cruise procedures:
1. The standard strategy,
2. The obstacle strategy,
3. Fixed speed strategies (ETOPS).

For ETOPS operations, any one of the above diversion strategies can be used provided that the selected strategy and speed schedule are used in :
- Establishing the area of operation (maximum diversion distance),
- Calculating the diversion fuel requirements for the single-engine ETOPS fuel scenario,
- Demonstrating the applicable obstacle clearance requirements (net flight path and net ceiling).

During the diversion, the flight crew is expected to use the planned speed schedule.
However, based on the evaluation of the actual situation, the pilot in command has the authority to deviate from this planned one-engine-inoperative speed.

GUIDELINES FOR DIVERSION PROCEDURE

Applicable to: ALL

- Complete the related failure procedure,
- Inform ATC,
- Initiate the descent,
- Determine which en route alternate is the most suitable (per company procedure),
- Divert to the chosen en route alternate,
- Comply with the pre-planned diversion strategy and speed schedule, or adjust the speed schedule, as dictated by the evaluation of the actual situation.

Note: For detailed guidelines and procedures for conducting the diversion (lateral and vertical navigation), Refer to DSC-22_20-60-60 Pilots/Stored Route Function, the FMGS Pilot's Guide.

GENERAL

Applicable to: ALL

The SOP (refer to chapter PRO-NOR-SOP) and the ABNORMAL and EMERGENCY procedures (refer to chapter PRO-ABN) to apply. For ETOPS flights, the flight crew must complete them using the procedure (*Refer to PRO-SPO-40-50 Cockpit Preparation*).

COCKPIT PREPARATION

Applicable to: B-HSD, B-HSE, B-HSG, B-HTF

FUEL

Before each flight, the flight crew must check that the fuel crossfeed valve is operating correctly :

FUEL X FEED .....ON

On the ECAM FUEL page, check that the fuel crossfeed valve is open (indication is inline green).

FUEL X FEED..... OFF

Check that the fuel crossfeed valve is closed.

AIR CONDITIONING

Packs flow selector must be on NORM or HI (LO selection is forbidden). This is to improve pressurization, if the normal electrical supply is lost.

COCKPIT PREPARATION

Applicable to: B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTG, B-HTH, B-HTI

FUEL

Before each flight, the flight crew must check that the fuel crossfeed valve is operating correctly :

FUEL X FEED .....ON

On the ECAM FUEL page, check that the fuel crossfeed valve is open (indication is inline green).

FUEL X FEED..... OFF

Check that the fuel crossfeed valve is closed.

ABN AND EMER PROCEDURES

Applicable to: ALL

ELECTRICAL EMERGENCY CONFIGURATION

In case of electrical emergency configuration, it may be better to study the STATUS on the paper checklist, after having applied ECAM actions.

The flight crew must complete the ECAM procedure using the following:

AIR CONDITIONING

As cockpit and cabin temperature control is lost, it is recommended to open the cockpit door.

FUEL

As all fuel pumps are lost, the engines are fed by gravity. *Refer to GRVTY FUEL FEEDING Procedure*.

ENGINE ANTI-ICE

Engine anti-ice valves are permanently open, although the ECAM memo ENG A. ICE is not displayed on the ECAM (except if the ENG A. ICE pb is at ON).

WING ANTI-ICE

If only one ENG BLEED is available, PACK 1 must be switched OFF, to avoid having both packs and wing anti-ice supplied by a single bleed source.

ENGINE

As the engines are in N1 unrated mode, the power setting has to be done using tables given in *Refer to PER-THR-N1 N1 MODE THRUST CONTROL*and following.

BLUE HYDRAULIC LOW LEVEL

Start the APU to ensure availability of the APU generator.

ENGINE OR IDG FAILURE

Start the APU and use the APU electrical channel.

GENERAL

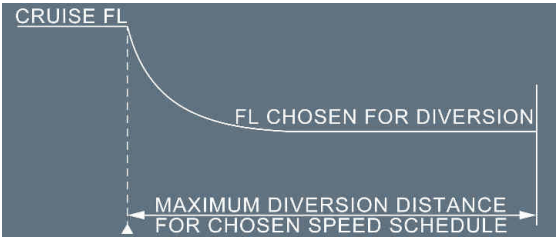
Applicable to: ALL

In case of electrical emergency configuration, the remaining engine reverts to N1 unrated mode. Consequently the penalties on net ceilings (*Refer to PER-THR-N1 MAXIMUM TAKEOFF N1*) must be taken into account for ETOPS part of the flight.

The two following cases result in a fuel consumption increase:
- RAT extended (*Refer to PRO-ABN-24 ELEC EMER CONFIG*)
- In electrical emergency configuration, the engine anti-ice valves are permanently open.

MAXIMUM DIVERSION DISTANCE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



The following computation conditions have been used in accordance with the interpretation of the EU-OPS 1.245 and FAR 121.161:

- ISA conditions
- No wind
- Optimum diversion level after engine failure
- Single engine diversion speed schedule.

Note: Obstacles have not to be considered to determine if a route is or is not an ETOPS route.

MAXIMUM DIVERSION DISTANCE

SPEED SCHEDULE	A/C WEIGHT AT CRITICAL POINT (KG)	FL FOR DIVERSION	DIVERSION TIME (MIN)					
			60	75	90	120	150	180

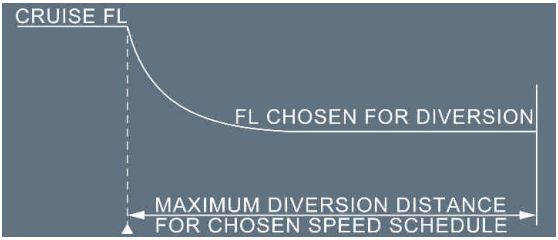
MAXIMUM DIVERSION DISTANCE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR



The following computation conditions have been used in accordance with the interpretation of the EU-OPS 1.245 and FAR 121.161:

- ISA conditions
- No wind
- Optimum diversion level after engine failure
- Single engine diversion speed schedule.

Note: Obstacles have not to be considered to determine if a route is or is not an ETOPS route.

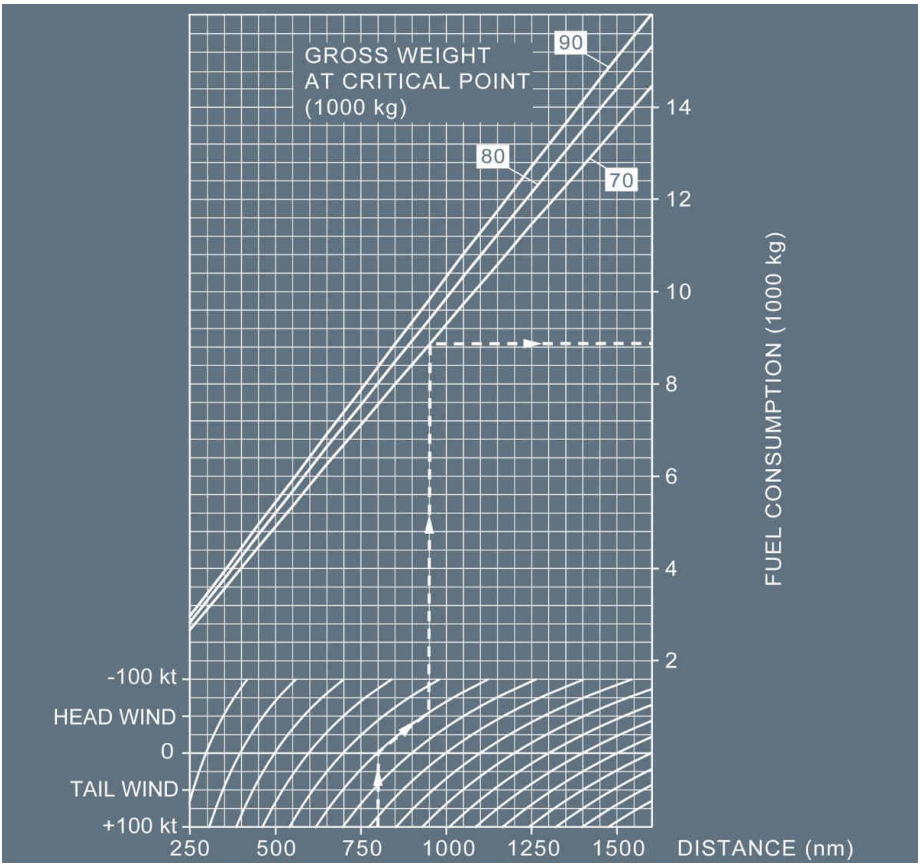
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ALL ENGINES - CRUISE AT LRC

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Assumptions:

- Emergency descent
- Long range cruise at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



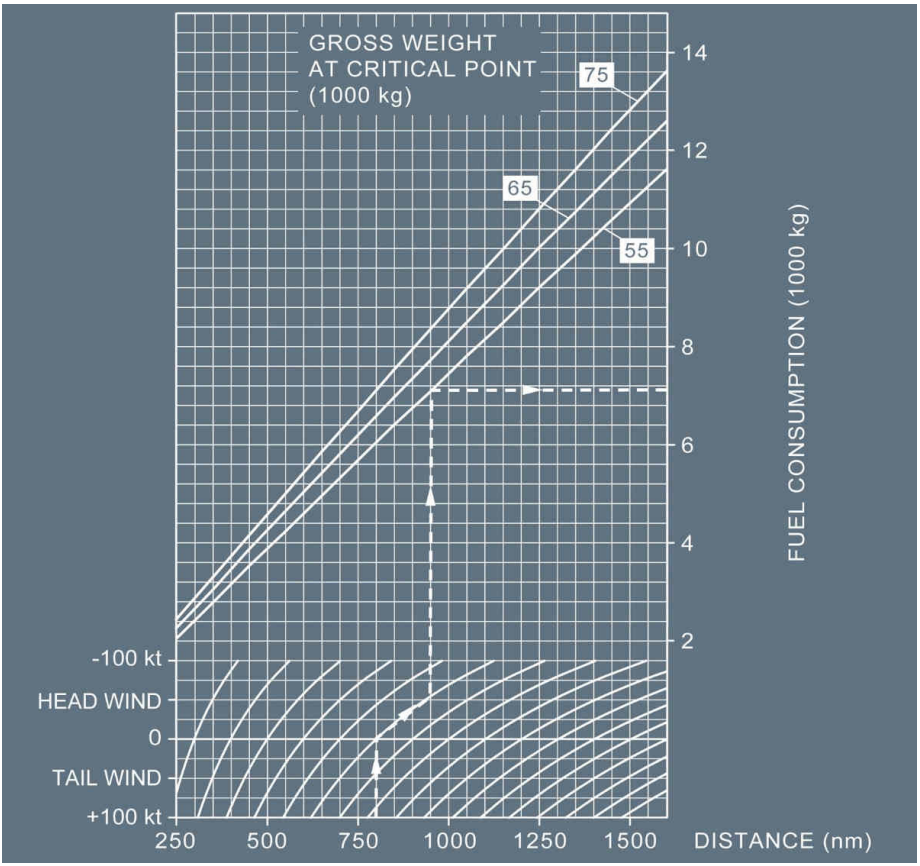
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ALL ENGINES - CRUISE AT LRC

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Assumptions:

- Emergency descent
- Long range cruise at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



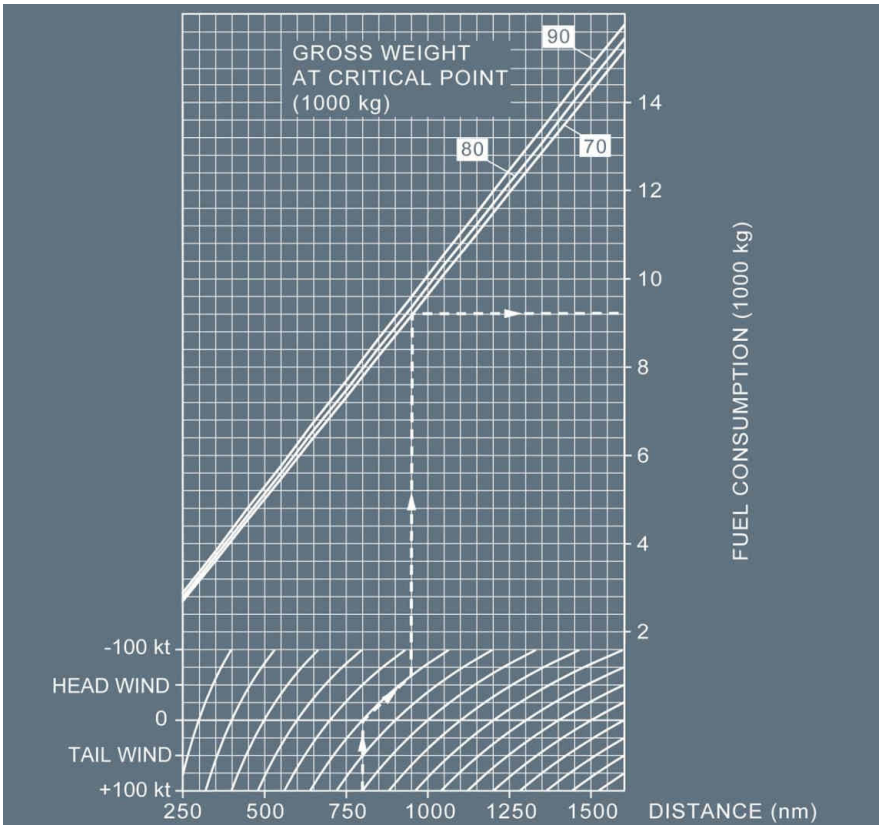
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ONE ENGINE OUT - CRUISE AT 350KT

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Assumptions:

- Emergency descent
- Cruise 350 kt at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure
- APU fuel burn.

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



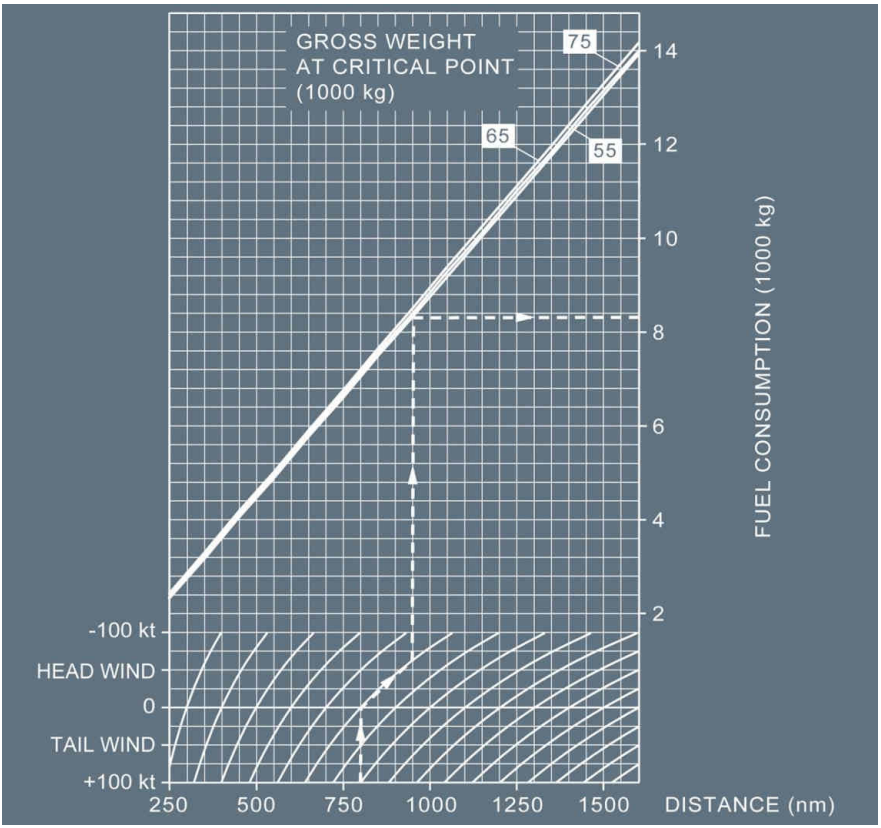
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ONE ENGINE OUT - CRUISE AT 350KT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Assumptions:

- Emergency descent
- Cruise 350 kt at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure
- APU fuel burn.

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



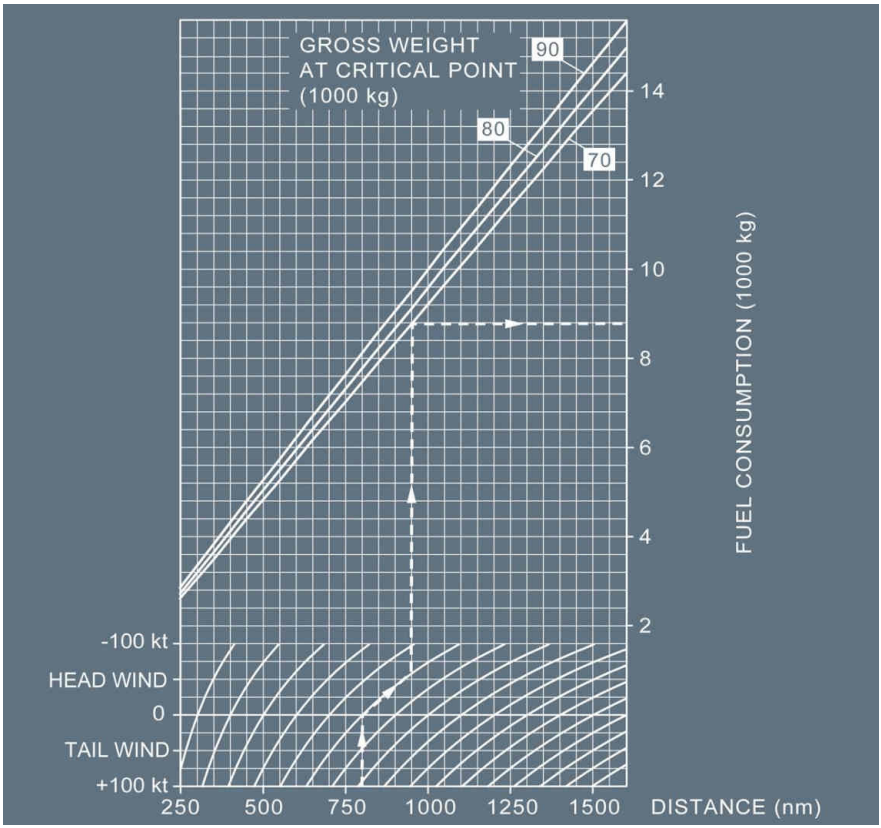
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ONE ENGINE OUT - CRUISE AT 320KT

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Assumptions:

- Emergency descent
- Cruise 320 kt at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure
- APU fuel burn.

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



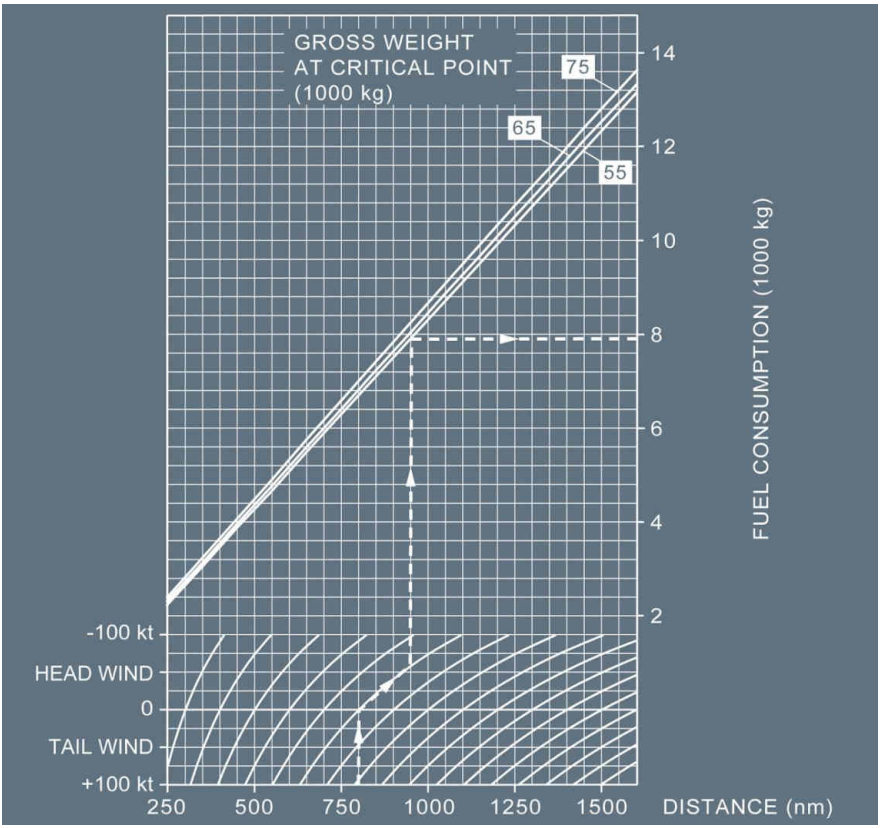
ETOPS FUEL FROM CRITICAL POINT TO LANDING - ONE ENGINE OUT - CRUISE AT 320KT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Assumptions:

- Emergency descent
- Cruise 320 kt at FL 100
- Final descent 250 kt
- Holding 15 min at FL 15
- IFR procedure
- APU fuel burn.

Not included: 5 % correction on wind value - Anti icing if icing is forecast - performance factor.



ETOPS FUEL REQUIREMENT FROM CRITICAL POINT TO LANDING - EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Assumptions:
- Aircraft weight at critical point: 70 000 kg
- Diversion speed: 320 kt
- Diversion time: 120 min
- Distance from Critical point to diversion airport: 700 nm
- Wind: 50 kt headwind
- Forecast icing condition on diversion: 40 min
- Aircraft perf factor: 5 %

For the determination of the ETOPS fuel requirement, the greatest fuel quantity of the two following scenarios must be considered (the scenario Engine failure only is never limiting):

1. Pressurization failure - One Engine Inoperative - 320 kt

- Determine the corrected wind for diversion taking into account the 5 % wind speed factor: 50 x 1.05 = 52.5 kt
- Enter the following ETOPS fuel requirement graph: *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - One Engine Out - Cruise at 320kt*
  Determine the corresponding fuel consumption: 7 600 kg
- Determine the final ETOPS fuel requirement, sum of perf factor fuel, icing fuel and fuel determined the step before:
  - Fuel for icing condition (Total anti-ice scenario is limiting): 4 % x 40 / 120 = 1.33 %
  - Fuel for perf factor: 5 %
  - Final ETOPS fuel requirement: 7 600 x 1.0133 x 1.05 = 8 087 kg

2. Pressurization failure - All Engines Operative - LRC speed

- Determine the corrected wind for diversion taking into account the 5 % wind speed factor: 50 x 1.05 = 52.5 kt
- Enter the following ETOPS fuel requirement graph: *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - All Engines - Cruise at LRC*
  Determine the corresponding fuel consumption: 7 800 kg
- Determine the final ETOPS fuel requirement, sum of perf factor fuel, icing fuel and fuel determined the step before:
  - Fuel for icing condition (total anti-ice scenario is limiting): 5 % x 40 / 120 = 1.67 %
  - Fuel for perf factor: 5 %
  - Final ETOPS fuel requirement: 7 800 x 1.0167 x 1.05 = 8 327 kg

The final ETOPS fuel requirement for this diversion is 8 327 kg. The limiting scenario is a pressurization failure and All Engines Operative at a diversion speed of LRC.

ETOPS FUEL REQUIREMENT FROM CRITICAL POINT TO LANDING - EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Assumptions:
- Aircraft weight at critical point: 65 000 kg
- Diversion speed: 320 kt
- Diversion time: 120 min
- Distance from Critical point to diversion airport: 700 nm
- Wind: 50 kt headwind
- Forecast icing condition on diversion: 40 min
- Aircraft perf factor: 5 %

For the determination of the ETOPS fuel requirement, the greatest fuel quantity of the two following scenarios must be considered (the scenario Engine failure only is never limiting):

1. Pressurization failure - One Engine Inoperative - 320 kt

   - Determine the corrected wind for diversion taking into account the 5 % wind speed factor: 50 x 1.05 = 52.5 kt
   - Enter the following ETOPS fuel requirement graph: *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - One Engine Out - Cruise at 320kt*
     Determine the corresponding fuel consumption: 6 900 kg
   - Determine the final ETOPS fuel requirement, sum of perf factor fuel, icing fuel and fuel determined the step before:

     • Fuel for icing condition (Total anti-ice scenario is limiting): 5 % x 40 / 120 = 1.67 %
     • Fuel for perf factor: 5 %
     • Final ETOPS fuel requirement: 6 900 x 1.0167 x 1.05 = 7 366 kg

2. Pressurization failure - All Engines Operative - LRC speed

- Determine the corrected wind for diversion taking into account the 5 % wind speed factor: 50 x 1.05 = 52.5 kt
- Enter the following ETOPS fuel requirement graph: *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - All Engines - Cruise at LRC*
  Determine the corresponding fuel consumption: 6 800 kg
- Determine the final ETOPS fuel requirement, sum of perf factor fuel, icing fuel and fuel determined the step before:
  - Fuel for icing condition (total anti-ice scenario is limiting): 5 % x 40 / 120 = 1.67 %
  - Fuel for perf factor: 5 %
  - Final ETOPS fuel requirement: 6 800 x 1.0167 x 1.05 = 7 260 kg

The final ETOPS fuel requirement for this diversion is 7 366 kg. The limiting scenario is a pressurization failure and One Engine Inoperative at a diversion speed of 320 kt.

GENERAL

Applicable to: ALL

Reduced Vertical Separation Minimum (RVSM) airspace is any airspace or route between FL 290 and FL 410 (inclusive), where aircraft are vertically separated by 1 000 ft, instead of 2 000 ft. The aircraft system design complies with the design criteria of the JAA Information Leaflet N° 6, and the FAA 91-RVSM Interim Guidance Material for RVSM operations.
The statement of RVSM capability is also indicated in the AFM.

OPERATIONAL APPROVAL

Applicable to: ALL

The above capability statement does not constitute an approval to fly RVSM. Operational approval is to be granted by the Operator's national authorities, after assessment of the airline's capability to meet RVSM requirements. The above-mentioned JAA and FAA documents also cover requirements for obtaining operational approval.

REQUIRED EQUIPMENT/FUNCTIONS FOR RVSM

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

RVSM regulations require the following equipment/functions in order to be operative :
- ADR1 + ADR2 + 2 DMC
- 1 transponder
- 1 Autopilot function
- 1 FCU channel (for altitude target selection and OP CLB/OP DES mode engagement)
- 2 PFD functions (for altitude indication)
- 1 FWC (for altitude alert function)

REQUIRED EQUIPMENT/FUNCTIONS FOR RVSM

Applicable to: B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

RVSM regulations require the following equipment/functions in order to be operative:
- 2 ADR + 2 DMC
- 1 transponder
- 1 Autopilot function
- 1 FCU channel (for altitude target selection and OP CLB/OP DES mode engagement)
- 2 PFD functions (for altitude indication)
- 1 FWC (for altitude alert function)

PROCEDURES

Applicable to: ALL

The SOPs (*Refer to 00010142 **Not found***) and the ABN and EMER (*Refer to PRO-ABN-01 Operational Recommendations*) procedures apply. In addition, flights in RVSM airspace must be completed by the following:

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

FLIGHT PREPARATION

The crew must pay particular attention to conditions that may affect operation in RVSM airspace. These include, but may not be limited to :

Verifying that the airframe is approved for RVSM operations.
Reported and forecast weather on the flight route.
Review of maintenance logs and forms to determine the condition of equipment required for flight in RVSM airspace. Ensure that maintenance action has been taken to correct any defects of required equipment.
Check that the PFD altitude indication (QNH reference) of ADR1, and also of ADR2, does not differ from the airport elevation by more than 75 ft.
Check, on ground, that the difference between the altitude indications from ADR1 and ADR2 is less than the tolerance specified in paragraph *Refer to PRO-SUP-34 Flight Instrument Tolerances - General* “Maximum Differences Between Altitude Indications”.

Applicable to: B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

FLIGHT PREPARATION

The crew must pay particular attention to conditions that may affect operation in RVSM airspace. These include, but may not be limited to :

Verifying that the airframe is approved for RVSM operations.
Reported and forecast weather on the flight route.
Review of maintenance logs and forms to determine the condition of equipment required for flight in RVSM airspace. Ensure that maintenance action has been taken to correct any defects of required equipment.
Check that the PFD altitude indication (QNH reference) of ADR1, and also of ADR2, does not differ from the airport elevation by more than 75 ft.
Check, on ground, that the difference between the two primary altitude indications is less than the tolerance specified in paragraph *Refer to PRO-SUP-34 Flight Instrument Tolerances - General* “Maximum Differences Between Altitude Indications”.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

PRIOR TO RVSM AIRSPACE ENTRY

The above-listed equipment for RVSM must be operating normally. Should any of this equipment fail prior entering the RVSM airspace, the crew must request new clearance, to avoid flight in this airspace. The two primary altitude indications (PFD indications from ADR1 and ADR2) should be in accordance with the instrument tolerance (*Refer to PRO-SUP-34 Flight Instrument Tolerances - General*). If only two ADRs are operative, the altimeter indications on the PFD and standby altimeters should be recorded. This information may be useful in case of subsequent PFD altitude discrepancies, or the loss of both remaining ADRs.

WITHIN RVSM AIRSPACE

- Autopilot should be engaged within RVSM airspace for cruise and flight level changes.
- During cleared transitions between flight levels, the aircraft should not overshoot or undershoot the cleared flight levels by more than 150 ft.
- At intervals of approximately one hour, check that PFD altimeter indications agree in accordance with the instrument tolerance (*Refer to PRO-SUP-34 Flight Instrument Tolerances - General*). The usual scan of flight deck instruments should be sufficient.
- Use the transponder and the autopilot, associated with one of the ADRs which is within tolerance.

Applicable to: B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

PRIOR TO RVSM AIRSPACE ENTRY

The above-listed equipment, for RVSM, must be operating normally. Should any of this equipment fail prior entering the RVSM airspace, the crew must request new clearance, to avoid flight in this airspace. The two primary altitude indications (PFD indications from the onside ADR, or ADR 3) should be in accordance with the instrument tolerance (*Refer to PRO-SUP-34 Flight Instrument Tolerances - General*). If only two ADRs are operative, the altimeter indications on the PFD and standby altimeters should be recorded. This information may be useful in case of subsequent PFD altitude discrepancies, or the loss of both remaining ADRs.

WITHIN RVSM AIRSPACE

- Autopilot should be engaged within RVSM airspace for cruise and flight level changes.
- During cleared transitions between flight levels, the aircraft should not overshoot or undershoot the cleared flight levels by more than 150 ft.
- At intervals of approximately one hour, check that PFD altimeter indications agree in accordance with the instrument tolerance (*Refer to PRO-SUP-34 Flight Instrument Tolerances - General*). The usual scan of flight deck instruments should be sufficient.
- Use the transponder and the autopilot, associated with one of the ADRs which is within tolerance.

Applicable to: ALL

The crew must report any malfunction of the height-keeping systems, including the:
- Malfunction or loss of any required equipment.
- Altimeter readings outside the tolerances of *Refer to PRO-SUP-34 Flight Instrument Tolerances - General*, and provide sufficient details to enable maintenance to troubleshoot and repair the system.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

When in RVSM airspace, the ATC will be notified of any of the following contingencies which affect the ability to maintain the cleared flight level.
- Failure of both autopilots,
- Loss of altimeter system redundancy (only one PFD indication remaining), or excessive altimeter discrepancy (200 ft).
- Failure of any other equipment affecting the ability to maintain the cleared flight level, or
- Encountering greater than moderate turbulence.
- Loss of ADR1 or ADR2. If ADR1 fails, use the AP2, if ADR2 fails, use AP1.
  If the AP is unable to maintain the assigned altitude, select the other AP.
- Loss of RVSM capability.

Note: *The flight crew can obtain the contingency procedures for flying in Minimum Navigation Performance Specification (MNPS) airspace by referring to specific manuals, such as, for example, the North Atlantic (NAT) MNPS Manual.*

If unable to notify ATC and obtain ATC clearance prior to deviating from the assigned cleared flight level, the crew should follow the established contingency procedure and obtain ATC clearance as soon as possible.

Applicable to: B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

When in RVSM airspace, the following contingencies which affect the ability to maintain the cleared flight level will be notified to ATC.
- failure of both autopilots,
- loss of altimeter system redundancy (only one PFD indication remaining), or excessive altimeter discrepancy (200 ft).
- failure of any other equipment affecting the ability to maintain the cleared flight level, or
- encountering greater than moderate turbulence.
- Loss of RVSM capability.

Note: *The flight crew can obtain the contingency procedures for flying in Minimum Navigation Performance Specification (MNPS) airspace by referring to specific manuals, such as, for example, the North Atlantic (NAT) MNPS Manual.*

If unable to notify ATC and obtain ATC clearance prior to deviating from the assigned cleared flight level, the crew should follow the established contingency procedure and obtain ATC clearance as soon as possible.

Intentionally left blank

GENERAL

Applicable to: ALL

GENERAL

The aircraft navigation system, required by regulation to fly within a Required Navigation Performance (RNP) airspace, shall comply with RNAV functionality criteria and with navigation position accuracy and integrity criteria.
When referring to RNP-X, the value of X is the navigation accuracy expressed in NM, which has to be met with a probability of 95 %.
An RNP value can be associated with an airspace, a route, a SID, a STAR, a RNAV approach, or an RNAV missed approach procedure.
Depending on the RNP value, and on the airspace environment (ground radio navaid), different navigation equipment may be necessary.
An operational approval from the airline's national authorities may be necessary.

Applicable to: ALL

NAVIGATION SYSTEM CAPABILITY (FOR REFERENCE ONLY)

European BRNAV (RNP-5) and P-RNAV (RNP-1) capability meets the certification requirements of JAA TGL 2 and TGL 10. Terminal and en-route RNAV operations comply with the certification requirements of the FAA Advisory Circular 90-100.
RNP-4 capability in oceanic or remote areas complies with FAA Notice 8400.33.
RNP-10 capability in oceanic or remote areas complies with paragraph 12.b (1) of FAA Notice 8400.12a., or with paragraph 12.a. or 12.b (5), if GPS is installed and is operative.
Navigation system with the GPS PRIMARY function (if GPS installed) meets the certification requirements of FAA AC 20-130A and TSO C 129A in class C1 (for navigation system with multiple sensor inputs including GPS).

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

RNP CAPABILITY

In order to match a given RNP value, the FMS-estimated position accuracy (also called Estimated Position Error) must be better than the RNP value. Obviously, this is dependent on the FMS navigation-updating mode (GPS/DME/DME, VORDME, or IRS).
On the MCDU PROG page, the required and the estimated position accuracy are displayed, and determine the HIGH/LOW accuracy indication (*Refer to DSC-22_20-20-20 Estimated Position Uncertainty*).
The required accuracy can be a default value, which is either a function of the flight phase, or a value manually-entered by the crew.
When flying in an RNP environment, the crew can insert the appropriate RNP value in the REQUIRED ACCUR field of the PROG page.

■ **When HIGH is displayed**

The RNP requirement is estimated to be fulfilled.

■ **When LOW is displayed**

The RNP requirement is estimated not to be fulfilled. In this case:
- The crew crosschecks navigation with raw data, if available,
- If the crosscheck is negative, or if raw data is unavailable, the crew informs the ATC.

When leaving the RNP environment, the crew will clear the manually-entered required accuracy.

WITHOUT GPS PRIMARY FUNCTION

RNP accuracy criteria are met, provided radio navaid coverage supports it for:
- RNP-1 en route and in the terminal area, provided a required accuracy of 1 nm See (1) is checked, or manually entered in the MCDU.
- RNP-0.3 in approach, provided a required accuracy of 0.3 nm See (1) is checked, or manually entered in the MCDU.

Note: *(1) It is possible to enter the radial equivalent to the specified Crosstrack (XTK) accuracy, that is the RNP multiplied by 1.2, the EPE being an estimated radial position error.*

WITH THE GPS PRIMARY FUNCTION

RNP requirements are met, provided GPS PRIMARY is available, for:
- RNP-1 en route
- RNP-0.5 in the terminal areas, provided the AP or FD in NAV mode is used.
- RNP-0.3 in approach, provided the AP or FD in NAV mode is used.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

RNP CAPABILITY

In order to match a given RNP value, the FMS-estimated position accuracy (also called Estimated Position Error) must be better than the RNP value. Obviously, this is dependent on the FMS navigation-updating mode (GPS/DME/DME, VORDME, or IRS).
On the MCDU PROG page, the required and the estimated position accuracy are displayed, and determine the HIGH/LOW accuracy indication (*Refer to DSC-22_20-20-20 Estimated Position Uncertainty*).
The required accuracy can be a default value, which is either a function of the flight phase, or a navigation database procedure value, or a value manually-entered by the crew.
When flying in an RNP environment, the crew can insert the appropriate RNP value in the REQUIRED ACCUR field of the PROG page.

■ **When HIGH is displayed**

The RNP requirement is estimated to be fulfilled.

■ **When LOW is displayed**

The RNP requirement is estimated not to be fulfilled. In this case :

- The crew crosschecks navigation with raw data, if available,
- If the crosscheck is negative, or if raw data is unavailable, the crew informs the ATC.

When leaving the RNP environment, the crew will clear the manually-entered required accuracy.

WITHOUT GPS PRIMARY FUNCTION

RNP accuracy criteria are met, provided radio navaid coverage supports it for :

- RNP-1 en route and in the terminal area, provided a required accuracy of 1 nm See (1) is checked, or manually entered in the MCDU.
- RNP-0.3 in approach, provided a required accuracy of 0.3 nm See (1) is checked, or manually entered in the MCDU.

Note: *(1) It is possible to enter the radial equivalent to the specified Crosstrack (XTK) accuracy, that is the RNP multiplied by 1.2, the EPE being an estimated radial position error.*

WITH THE GPS PRIMARY FUNCTION

RNP requirements are met, provided GPS PRIMARY is available, for :

- RNP-1 en route
- RNP-0.5 in the terminal areas, provided the AP or FD in NAV mode is used.
- RNP-0.3 in approach, provided the AP or FD in NAV mode is used.

BRNAV IN EUROPEAN AIRSPACE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

In this airspace, radio navaid coverage is assumed to support RNP-5 accuracy.

The minimum required equipment to enter BRNAV airspace is :

- One RNAV system, which means :
  - One FMGC
  - One MCDU
  - One VOR for FM navigation update
  - One DME for FM navigation update
  - One IRS
- In addition:
  - On the PF side : PFD and ND must be operative.
  - On the PNF side : at least one of the two EFIS must be operative (to enable temporary display of ND information through the PFD/ND switch).

PROCEDURES

When GPS PRIMARY is not available, periodically crosscheck the FM position with navaid raw data.

Manual selection of a required accuracy on the MCDU is optional.

- **If manual entry of a required accuracy is desired** enter 5 nm or use the radial equivalent to 5 nm XTK accuracy, that is 6.1 nm.
  - **When leaving RNP-5 airspace, or when entering the terminal area** revert to the default required accuracy, or enter the appropriate value on the MCDU.
- **If one of the following MCDU or ECAM messages is displayed**

  check navigation accuracy with navaid raw data, or with the GPS MONITOR page (if GPS installed) :
  - NAV ACCUR DOWNGRAD
  - FMS1/FMS2 POS DIFF
  - CHECK A/C POSITION
  - ECAM : FM/GPS POS DISAGREE (if GPS installed)
- **If the accuracy check confirms that RNP-5 capability is lost, or if both FMGCs have failed** Inform the ATC, and revert to conventional navigation.
- **If the accuracy check confirms that only one FMGC position is incorrect** , resume navigation with the other FMGC.

In inertial navigation, BRNAV capability is maintained for 2 h, independently of the estimated accuracy displayed on the MCDU.

BRNAV IN EUROPEAN AIRSPACE

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

In this airspace, radio navaid coverage is assumed to support RNP-5 accuracy.

The minimum required equipment to enter BRNAV airspace is :

- One RNAV system, which means :
  - One FMGC
  - One MCDU
  - One VOR for FM navigation update
  - One DME for FM navigation update
  - One IRS
- In addition:
  - On the PF side : PFD and ND must be operative.
  - On the PNF side : at least one of the two EFIS must be operative (to enable temporary display of ND information through the PFD/ND switch).

PROCEDURES

When GPS PRIMARY is not available, periodically crosscheck the FM position with navaid raw data.
Manual selection of a required accuracy on the MCDU is optional.

- **If manual entry of a required accuracy is desired** enter 5 nm or use the radial equivalent to 5 nm XTK accuracy, that is 6.1 nm.
  - **When leaving RNP-5 airspace, or when entering the terminal area** revert to the default required accuracy, or enter the appropriate value on the MCDU.
- **If one of the following MCDU or ECAM messages is displayed**

  check navigation accuracy with navaid raw data, or with the GPS MONITOR page (if GPS installed) :
  - NAV ACCUR DOWNGRAD
  - FMS1/FMS2 POS DIFF
  - CHECK IRS 1(2)(3)/FM POSITION
  - ECAM : FM/GPS POS DISAGREE (if GPS installed)
- **If the accuracy check confirms that RNP-5 capability is lost, or if both FMGCs have failed** Inform the ATC, and revert to conventional navigation.
- **If the accuracy check confirms that only one FMGC position is incorrect** , resume navigation with the other FMGC.

In inertial navigation, BRNAV capability is maintained for 2 h, independently of the estimated accuracy displayed on the MCDU.

RNP-4 OR RNP-10 IN OCEANIC OR REMOTE AREAS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

In this kind of airspace, the aircraft is expected to fly for a long period of time outside radio navaid coverage.

The minimum required equipment to enter a RNP-4/RNP-10 airspace is:

- Two long range navigation systems, which means:
  - Two FMGC (or 1 FMGC + 1 BACK UP NAV)
  - Two MCDU
  - For RNP-10, one GPS if required by flight time outside radio navaid coverage. For aircraft without GPS the flight time outside radio navaid coverage is limited. According to FAA Notice 8400.12A, this limitation is:
    - 6.2 h since IRS ground alignment, or
    - 5.7 h since last FM radio update.

    There is no limitation for aircraft fitted with the GPS.
    For RNP-4, one GPS is required.
  - Two IRS
  - Two NDs to display Flight Plan Data.

Refer also to Regional Supplementary Procedures of ICAO Doc 7030 for specific requirements in a particular airspace.

PROCEDURES

The Manual selection of a required accuracy on the MCDU is optional.

- **If manual entry of a required accuracy is desired, the flight crew must manually enter:**
  For RNP-10, enter 10 nm or use the radial equivalent to 10 nm XTK accuracy that is 12.2 nm.
  For RNP- 4, enter 4 nm or use the radial equivalent to 4 nm XTK accuracy that is 4.9 nm.
- **When leaving RNP airspace,** revert to the default required accuracy or enter the appropriate value.
- **If one of the following MCDU or ECAM messages is displayed,**

  check navigation with POSITION MONITOR page, ISDU and GPS MONITOR page (if GPS installed) :
  - FMS1/FMS2 POS DIFF
  - CHECK A/C POSITION
  - ECAM : FM/GPS POS DISAGREE (if GPS installed)

Use the AP, with the navigation system checked correct.

- **If unable to determine which system is correct,** inform the ATC, and look for navaid raw data confirmation as soon as possible.

In inertial navigation, the RNP -10 capability is maintained for 5.7 h, since the last radio update (according to FAA Notice 8400.12A), independently of the estimated accuracy displayed on the MCDU.
For RNP-4 with GPS PRIMARY LOST, the RNP-4 capability is maintained until NAV ACCUR DOWNGRAD appears.

RNP-4 OR RNP-10 IN OCEANIC OR REMOTE AREAS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

In this kind of airspace, the aircraft is expected to fly for a long period of time outside radio navaid coverage.

The minimum required equipment to enter a RNP-4/RNP-10 airspace is:
- Two long range navigation systems, which means:
  - Two FMGC (or 1 FMGC + 1 BACK UP NAV)
  - Two MCDU
  - For RNP-10, one GPS if required by flight time outside radio navaid coverage. For aircraft without GPS the flight time outside radio navaid coverage is limited. According to FAA Notice 8400.12A, this limitation is:
    - 6.2 h since IRS ground alignment, or
    - 5.7 h since last FM radio update.

    There is no limitation for aircraft fitted with the GPS.
    For RNP-4, one GPS is required.
  - Two IRS
  - Two NDs to display Flight Plan Data.

Refer also to Regional Supplementary Procedures of ICAO Doc 7030 for specific requirements in a particular airspace.

PROCEDURES

Manual selection of a required accuracy on the MCDU is optional.

- **If manual entry of a required accuracy is desired, the flight crew must manually enter:**
  For RNP-10, enter 10 nm or use the radial equivalent to 10 nm XTK accuracy that is 12.2 nm.
  For RNP- 4, enter 4 nm or use the radial equivalent to 4 nm XTK accuracy that is 4.9 nm.
- **When leaving RNP airspace** revert to the default required accuracy or enter the appropriate value.

- **If one of the following MCDU or ECAM messages is displayed,**

  check navigation with POSITION MONITOR page, ISDU or IRS 1(2)(3) pages, and GPS MONITOR page (if GPS installed) :
  - FMS1/FMS2 POS DIFF
  - CHECK IRS 1(2)(3)/FM POSITION
  - ECAM : FM/GPS POS DISAGREE (if GPS installed)

  Use the AP, with the navigation system checked correct.

- **If unable to determine which system is correct,** inform the ATC, and look for navaid raw data confirmation as soon as possible.

In inertial navigation, the RNP -10 capability is maintained for 5.7 h, since the last radio update (according to FAA Notice 8400.12A), independently of the estimated accuracy displayed on the MCDU.
For RNP-4 with GPS PRIMARY LOST, the RNP-4 capability is maintained until NAV ACCUR DOWNGRAD appears.

P-RNAV/RNP-1 TERMINAL PROCEDURES

Applicable to: ALL

For terminal procedures requiring P-RNAV or RNP-1 capability, the flight crew can assume that the radio navaid coverage supports the RNP-1 accuracy. Otherwise, the procedure may specify that GPS equipment is required (refer to the published procedure chart).

The minimum equipment required to fly a P-RNAV or RNP-1 procedure is:
- One RNAV system, which includes:
  - One FMGC
  - One MCDU
  - One GPS receiver, or one VOR and one DME, for FM navigation update See *
  - Two IRS, and
  - One FD in NAV mode.
- In addition:
  - On the PF side : PFD and ND must be operative.
  - On the PNF side : at least one of the two EFIS must be operative (to enable temporary display of ND information through the PFD/ND switch).

*GPS may be required for RNP-1 terminal procedures.
For terminal procedures with legs below the MSA, or with legs that may not have sufficient radar coverage, two RNAV systems may be mandated by the procedure chart.

PROCEDURES

The terminal procedure (RNAV SID, RNAV STAR, RNAV TRANSITION, ...) must be loaded from the FM navigation database and checked for reasonableness, by comparing the waypoints, tracks, distances and altitude constraints (displayed on the F-PLN page), with the procedure chart.
The flight crew must not modify the procedure, that is loaded from the navigation database, unless instructed to do so by the ATC (DIR TO, radar vectoring, insertion of waypoints loaded from the navigation database).

■ **If GPS is required for the P-RNAV/RNP-1 procedure :**

Before starting the departure/approach procedure, check that GPS PRIMARY is available (GPS PRIMARY displayed on the MCDU PROG page).

- **If GPS PRIMARY is not available before starting the procedure** inform the ATC, and request another departure/arrival procedure that does not require GPS.
- **If GPS PRIMARY is lost while flying the procedure** inform the ATC of this loss of capability, and follow ATC instructions.

■ **If GPS is NOT required for the P-RNAV/RNP-1 procedure :**

Check that GPS PRIMARY is available (GPS PRIMARY displayed on the MCDU PROG page).

- **IF GPS PRIMARY is not available:**
  Crosscheck the FM position with the navaid raw data, before starting the procedure. Check or enter RNP-1 in the REQUIRED field of the MCDU PROG page, and check that HIGH accuracy is available. When completing the terminal procedure, revert to the default value or enter the appropriate value on the MCDU PROG page.
- **If one of the following messages appears,**

  while flying the procedure:
  - "NAV ACCUR DOWNGRAD" (on MCDU and ND) on both sides, or
  - "FMS1/FMS2 POS DIFF" (on MCDU), or
  - "CHECK IRS 1(2)(3)/FM POSITION" (on MCDU), or
  - "NAV FM/GPS POS DISAGREE" (on ECAM, if GPS installed)

Then:

Inform the ATC of the loss of P-RNAV/RNP-1 capability, and follow ATC instructions.

Note: *If the "NAV ACCUR DOWNGRAD" message is displayed on one side only, navigation may be continued using the other FMGC.*

Intentionally left blank

GENERAL

Applicable to: ALL

This chapter gives the limitations, procedures and performance for operations from/to runways with a width below 45 m .
This chapter does not constitute an operational approval to operate on narrow runways.
Such authorization must be obtained by the operator from the appropriate authorities.

LIMITATIONS

Applicable to: ALL

Minimum runway width..... 30 m

The dispatch from/to narrow runways is not allowed in case of :
- Nose wheel steering inoperative
- One brake or more inoperative

Autoland is not allowed.

PROCEDURES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Diversion to a 45 m wide runway is recommended in case of :
- Rudder jam
- Rudder pedal jam
- Yaw damper system fault
- All failures leading to the loss of the nose wheel steering (HYD Green system loss, double hydraulic failure, double BSCU fault, double LGCIU fault)

Maximum demonstrated crosswind for takeoff and landing:

Dry runway.....38 kt (gust included) for takeoff and landing
Wet runway.....33 kt (gust included) for takeoff and landing
Contaminated runway..... 10 kt (gust included) for takeoff and landing

Note: *These maximum demonstrated crosswind values are based on the assumption that the crew have been trained accordingly.*

Operations on icy runways have not been demonstrated.

PROCEDURES

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

Diversion to a 45 m wide runway is recommended in case of :

- Rudder jam
- Rudder pedal jam
- Yaw damper system fault
- All failures leading to the loss of the nose wheel steering (HYD Yellow system loss, double hydraulic failure, double BSCU fault, double LGCIU fault)

Maximum demonstrated crosswind for takeoff and landing:

Dry runway.....38 kt (gust included) for takeoff and landing
Wet runway.....33 kt (gust included) for takeoff and landing
Contaminated runway..... 10 kt (gust included) for takeoff and landing

Note: *These maximum demonstrated crosswind values are based on the assumption that the crew have been trained accordingly.*

Operations on icy runways have not been demonstrated.

PERFORMANCE

Applicable to: ALL

For runways with a width above or equal to 40 m ., the basic takeoff performance remains unchanged.
For runways with a width below 40 m , the VMCG must be increased by the values indicated in the following table :

Runway Width	30 m	35 m	40 m
△VMCG (kt)	+ 2.5	+ 1.5	+ 0

No correction is required, when takeoff performance is determined by using the applicable approved data.
The minimum V1 values, published in the *Refer to PER-TOF-TOD-25-10 SPEEDS LIMITED BY VMC*, must be increased by 3 kt .
When using the takeoff performance for contaminated runways *Refer to PER-TOF-CTA-10 GENERAL*, or the quick reference tables (*Refer to PER-TOF-TOD-40-10 INTRODUCTION*), the resulting V1 must be crosschecked with the corrected minimum V1.
Further decrease the takeoff weight by 3 t per knot increase in V1.

GENERAL

Applicable to: ALL

ILS Precision Runway Monitoring (PRM) approaches can be performed when the airport is equipped with the PRM system. This system enables the ATC to control simultaneous close parallel ILS approaches. The air traffic controllers use the PRM system to monitor the flight path of aircraft that fly parallel approaches. They can check that aircraft do not penetrate the Non Transgression Zone (NTZ) located between the two localizers. If an aircraft penetrates this NTZ, the ATC orders the other parallel aircraft to breakout.

REQUIREMENTS

Applicable to: ALL

- 2 VHF must be operative
- The flight crew must be trained
- Before the approach, the flight crew has to review the ILS PRM approach chart and procedures, and in particular the “Attention All Users” pages for the flight safety.
- The flight crew must know specific breakout phraseology and be ready to apply specific breakout procedures.

BREAKOUT PROCEDURE

Applicable to: ALL

- When the ATC orders so, the breakout is mandatory for the flight safety, considering adjacent aircraft position and trajectory. It requires an immediate response.
- Breakout must be hand-flown
- Breakout orders always include a turn order, and a “climb” or “descent” order depending on what is the most suitable.

BREAKOUT TURN AND CLIMB PROCEDURE

Simultaneously

AP.....OFF
BREAKOUT LEFT (RIGHT), HDGxxx, ALTyyy.....ANNOUNCE
THR LEVERS.....TOGA and back to CL

The SRS GA and GA TRK modes engage. The THR CLB mode engages. The speed is managed. The speed target is the aircraft speed at SRS GA engagement. The FMS GO-AROUND phase becomes active. Thus, the FMS reinserts the approach.

TURN LEFT (RIGHT) AND CLIMB
As the situation is urgent, the flight crew should temporarily not follow the FD orders.

Then

HDGxxx.....TURN & PULL

The GA TRK mode disengages, and the HDG mode engages.

ALTyyy.....TURN & PULL

The SRS GA mode disengages, and the OP CLB mode engages. The speed target becomes the FMS speed target of the CLIMB phase.

SPEED.....PULL AND ADJUST

For the initial breakout procedure, adjust the speed (e.g. 160 kt), in order to avoid an important acceleration, and an increase of workload.

- **When established on the breakout path:**

  AP.....ON

  Before engaging the AP, ensure that the FD bar orders approximately correspond to the aircraft current path.

  SPEED.....SELECT AS RQRD
  FLAPS.....AS RQRD
  GEAR.....AS RQRD
  TCAS MODE SEL.....TA/RA

BREAKOUT TURN AND DESCENT PROCEDURE

Simultaneously

AP.....OFF
TURN LEFT (RIGHT) AND MAINTAIN RATE OF DESCENT
BREAKOUT LEFT (RIGHT), HDGxxx, ALTyyy.....ANNOUNCE

As the situation is urgent, the flight crew should temporarily not follow the FD orders.

Then

HDGxxx.....TURN & PULL

The HDG mode engages. The vertical mode reverts to V/S. The vertical speed target is the aircraft vertical speed at V/S engagement.

ALTyyy..... TURN & PULL

This action defines an altitude target. The OP DES mode and the THR IDLE mode engage. The speed target does not change.

V/S.....MONITOR

CAUTION	*Depending on the speed target, the vertical speed may become excessive. If the rate of descent exceeds 1 000 ft/min, engage the V/S mode and limit the rate of descent to 1 000 ft/min.*

- **When established on the breakout path:**

  AP.....ON

  Before engaging the AP, ensure that the FD bar orders approximately correspond to the aircraft current path.

- **When cleared by ATC:**

  ALTyyy.....TURN

  Select an altitude target for go-around, in accordance with the ATC clearance.

  THR LEVERS.....TOGA and back to CL

  The SRS GA and GA TRK modes engage. The THR CLB mode engages. The speed is managed. The speed target is the aircraft speed at SRS GA engagement. The FMS GO-AROUND phase becomes active.

  HDGxxx ..... PULL

  The GA TRK mode disengages, and the HDG mode engages. The SRS GA mode remains engaged, until ALT engagement.*

  SPEED.....SELECT AS RQRD
  FLAPS.....AS RQRD
  GEAR.....AS RQRD
  TCAS MODE SEL.....TA/RA

IN-FLIGHT VIBRATION REPORTING

Applicable to: ALL

CAUTION	There is no requirement to carry out any specific manoeuvre to ascertain the effect of flight control inputs on airframe vibrations. Completion of the Vibration Reporting form should be based on observations made during normal flight conditions. The autopilot should not be disconnected to fascilitate the assessment process.

In-flight vibration events whether transient or continuous need to be actioned by Engineering in a timely fashion. Under normal circumstances an initial AML entry triggers Engineering troubleshooting and rectification.
To expedite the process and ensure detailed event information is reported, a “Vibration Reporting Sheet” form [ENG/MC/VIB] is carried in the ENG documents folder.

For all vibration events, an AML entry must be made detailing the basic event details.
- Make use of the form to detail the parameters required to allow timely follow-up action from Engineering.
- At the end of the flight, any completed forms must be left in the AML for the receiving Engineer’s action.
- If nil forms are present, raise a AML entry to that effect and record the following parameters:

  • Aircraft Speed (kts)
  • Flight Phase (INITIAL/CLIMB/CRUISE/DESCENT/APPROACH)
  • Slat/Flap Position (0, 1, 2, 3 or FULL)
  • Flight Control Oscillations visible on ECAM (YES/NO). If “YES”, detail which flight control surface.
  • Affected Area (Cockpit, FWD, MID or AFT Cabin)
  • Audible Noise (YES/NO)

FORM No: ENG/MCVIB Rev 00

GENERAL

Applicable to: ALL

This chapter shows the speed symbols and definitions.
The source of the computation is also given, when applicable.

CHARACTERISTIC SPEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The characteristic speeds displayed on the PFD are computed by the Flight Augmentation Computer (FAC), according to the FMS weight data (for PFD/MCDU display consistency and accuracy purposes), and aerodynamic data as a backup.
VLS (of normal landing configuration: CONF 3 or FULL), F, S, and Green Dot speeds are also displayed on the MCDU TAKEOFF and/or APPR pages.
These values are computed by the FMS, based on the aircraft gross weight (which is computed according to the entered ZFW and the FOB), or the predicted grossweight (for approach or go-around).

VS : Stalling speed.
Not displayed.
For a conventional aircraft, the reference stall speed, VSmin, is based on a load factor that is less than 1 g. This gives a stall speed that is lower than the stall speed at 1 g. All operating speeds are expressed as functions of this speed (for example, VREF = 1.3 VSmin).
Because aircraft of the A320 family have a low-speed protection feature (alpha limit) that the flight crew cannot override, Airworthiness Authorities have reconsidered the definition of stall speed for these aircraft.
All the operating speeds must be referenced to a speed that can be demonstrated fight tests. This speed is designated VS1g.

Airworthiness Authorities have agreed that a factor of 0.94 represents the relationship between VS1g for aircraft of the A320 family and VSmin for conventional aircraft types. As a result, Authorities allow aircraft of the A320 family to use the following factors:
- V2 = 1.2 × 0.94 VS1g = 1.13 VS1g
- VREF = 1.3 × 0.94 VS1g = 1.23 VS1g

These speeds are identical to those that the conventional 94 % rule would have defined for these aircraft. The A318, A319, A320, and A321 have exactly the same maneuver margin that a conventional aircraft would have at its reference speeds.
The FCOM uses VS for VS1g.

VLS : Lowest Selectable Speed.
Represented by the top of an amber strip along the airspeed scale on the PFD.
Computed by the FAC, based on aerodynamic data, and corresponds to 1.13 VS during takeoff, or after a touch and go.
Becomes 1.23 VS, after retraction of one step of flaps.
Becomes 1.28 VS, when in clean configuration.

Note: *If in CONF 0 VLS were 1.23 VS (instead of 1.28 VS), the alpha protection strip would hit the VLS strip on the PFD.*

Above 20 000 ft, VLS is corrected for Mach effect to maintain a buffet margin of 0.2 g.
In addition, VLS increases with speed brakes extension.

F : Minimum speed at which the flaps may be retracted at takeoff.
In approach, used as a target speed when the aircraft is in CONF 2 or CONF 3.
Represented by "F" on the PFD speed scale. Equal to about 1.23 VS of CONF 1 + F.

S : Minimum speed at which the slats may be retracted at takeoff.
In approach, used as a target speed when the aircraft is in CONF 1.
Represented by "S" on the PFD airspeed scale.
Equal to about 1.29 VS of clean configuration.

O : Green dot speed.
Engine-out operating speed in clean configuration.
(Best lift-to-drag ratio speed).
Also corresponds to the final takeoff speed.
Represented by a green dot on the PFD scale.
Below 20 000 ft equal to 2 × weight (tons) +80
Above 20 000 ft, add 1 kt per 1 000 ft

CHARACTERISTIC SPEEDS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The characteristic speeds displayed on the PFD are computed by the Flight Augmentation Computer (FAC), according to the FMS weight data (for PFD/MCDU display consistency and accuracy purposes), and aerodynamic data as a backup.
VLS (of normal landing configuration: CONF 3 or FULL), F, S, and Green Dot speeds are also displayed on the MCDU TAKEOFF and/or APPR pages.
These values are computed by the FMS, based on the aircraft gross weight (which is computed according to the entered ZFW and the FOB), or the predicted grossweight (for approach or go-around).

VS : Stalling speed.
Not displayed.
For a conventional aircraft, the reference stall speed, VSmin, is based on a load factor that is less than 1 g. This gives a stall speed that is lower than the stall speed at 1 g. All operating speeds are expressed as functions of this speed (for example, VREF = 1.3 VSmin).
Because aircraft of the A320 family have a low-speed protection feature (alpha limit) that the flight crew cannot override, Airworthiness Authorities have reconsidered the definition of stall speed for these aircraft.
All the operating speeds must be referenced to a speed that can be demonstrated fight tests. This speed is designated VS1g.

Airworthiness Authorities have agreed that a factor of 0.94 represents the relationship between VS1g for aircraft of the A320 family and VSmin for conventional aircraft types. As a result, Authorities allow aircraft of the A320 family to use the following factors:
- V2 = 1.2 × 0.94 VS1g = 1.13 VS1g
- VREF = 1.3 × 0.94 VS1g = 1.23 VS1g

These speeds are identical to those that the conventional 94 % rule would have defined for these aircraft. The A318, A319, A320, and A321 have exactly the same maneuver margin that a conventional aircraft would have at its reference speeds.
The FCOM uses VS for VS1g.

VLS : Lowest Selectable Speed.
Represented by the top of an amber strip along the airspeed scale on the PFD.
Computed by the FAC, based on aerodynamic data, and corresponds to 1.13 VS during takeoff, or after a touch and go.
Becomes 1.23 VS, after retraction of one step of flaps.
Becomes 1.28 VS, when in clean configuration.

Note: *If in CONF 0 VLS were 1.23 VS (instead of 1.28 VS), the alpha protection strip would hit the VLS strip on the PFD.*

Above 20 000 ft, VLS is corrected for Mach effect to maintain a buffet margin of 0.2 g.
In addition, VLS increases with speed brakes extension.

F : Minimum speed at which the flaps may be retracted at takeoff.
In approach, used as a target speed when the aircraft is in CONF 2 or CONF 3.
Represented by “F” on the PFD speed scale. Equal to about 1.19 VS of CONF 1 + F.

S : Minimum speed at which the slats may be retracted at takeoff.
In approach, used as a target speed when the aircraft is in CONF 1.
Represented by “S” on the PFD airspeed scale.
Equal to about 1.25 VS of clean configuration.

O : Green dot speed.
Engine-out operating speed in clean configuration.
(Best lift-to-drag ratio speed).
Also corresponds to the final takeoff speed.
Represented by a green dot on the PFD scale.
Below 20 000 ft equal to 1.5 × weight (tons) + 110
Above 20 000 ft, add 1 kt per 1 000 ft

PROTECTION SPEEDS

Applicable to: ALL

Vα PROT, Vα MAX and VSW are computed by the FAC, based on aerodynamic data. They are only used for display on the PFD, and not for flight control protection (the activation of the protections is computed by the ELAC).

Vα PROT : Angle of attack protection speed.
Corresponds to the angle of attack at which the angle of attack protection becomes active.
Represented by the top of a black and amber strip along the PFD speed scale, in normal law.

Vα MAX : Maximum angle of attack speed.
Corresponds to the maximum angle of attack that may be reached in pitch normal law.
Represented by the top of a red strip along the PFD speed scale, in normal law.

VSW : Stall warning speed.
Represented by a red and black strip along the speed scale when the flight control normal law is inoperative.

VMAX : Represented by the bottom of a red and black strip along the speed scale.
Determined by the FAC according to the aircraft configuration.
Is equal to VMO (or speed corresponding to MMO), VLE or VFE.

LIMIT SPEEDS

Applicable to: ALL

VA : Maximum design maneuvering speed. This corresponds to the maximum structural speed permitted for full control deflection, if alternate or direct law is active.

VMCG : Minimum speed, on the ground during takeoff, at which the aircraft can be controlled by only using the primary flight controls, after a sudden failure of the critical engine, the other engine remaining at takeoff power.

VMCA : Minimum control speed in flight at which the aircraft can be controlled with a maximum bank of 5 °, if one engine fails, the other engine remaining at takeoff power (takeoff flap setting, gear retracted).

VMCL : Minimum control speed in flight, at which the aircraft can be controlled with a maximum bank of 5 °, if one engine fails, the other engine remaining at takeoff power (approach flap setting).

VFE : Maximum speed for each flap configuration.

VLE : Maximum speed with landing gear extended.

VLO : Maximum speed for landing gear operation.

VMO : Maximum speed.

VFE NEXT : Maximum speed for the next (further extended) flap lever position.

OTHER SPEEDS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

V1 : The highest speed, during takeoff, at which the flight crew has a choice between continuing the takeoff or stopping the aircraft.
Represented by "1" on the airspeed scale (or the V1 value when it is off the airspeed scale).
Inserted manually through the MCDU by the flight crew.
Displayed on the MCDU TAKEOFF page.

VR : The speed at which the pilot rotates in order to reach V2 at an altitude of 35 ft at the latest after an engine failure.
Inserted manually through the MCDU by the flight crew.
Displayed on the MCDU TAKEOFF page.

V2 : Takeoff safety speed that the aircraft attains at the latest at an altitude of 35 ft with one engine failed, and maintains during the second segment of the takeoff.
Represented by the SPEED SELECT symbol on the speed scale.
Minimum value equal to 1.13 VS for the corresponding configuration.
Inserted manually through the MCDU by the flight crew.
Displayed on the MCDU TAKEOFF page.

VREF : Reference speed used for normal final approach.
Equal to 1.23 × VS of CONF FULL.
Displayed on the MCDU APPR page, if landing is planned in CONF FULL (VLS CONF FULL).

VAPP : Final approach speed.
Displayed on MCDU APPR page.
Calculated by the FMGCs.
Represents : VAPP = VLS + wind correction.
The wind correction is limited to a minimum of 5 kt and a maximum of 15 kt.
The flight crew may modify VAPP through the MCDU.

- During autoland or when A/THR is on or in case of ice accretion or gusty crosswing greater than 20 kt, VAPP must not be lower than VLS +5 kt.
- For landing in configuration 3 with ice accretion VAPP must not be lower than VLS +10 kt.

VAPP TARGET : Represented by a magenta triangle.
Calculated by the FMGCs
Gives efficient speed guidance in approach during various windy conditions.
Represents :
VAPP TARGET = GS mini + actual headwind (measured by ADIRS)
GS mini = VAPP – TOWER WIND (headwind component along runway axis calculated by FMGC from tower wind entered on MCDU).

OTHER SPEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

V1 : The highest speed, during takeoff, at which the flight crew has a choice between continuing the takeoff or stopping the aircraft.
Represented by “1” on the airspeed scale (or the V1 value when it is off the airspeed scale).
Inserted manually through the MCDU by the flight crew at the latest.
Displayed on the MCDU TAKEOFF page.

VR : The speed at which the pilot rotates in order to reach V2 at an altitude of 35 ft at the latest after an engine failure.
Inserted manually through the MCDU by the flight crew.
Displayed on the MCDU TAKEOFF page.

V2 : Takeoff safety speed that the aircraft attains at the latest at an altitude of 35 ft with one engine failed, and maintains during the second segment of the takeoff.
Represented by the SPEED SELECT symbol on the speed scale.
Minimum value equal to 1.13 VS for the corresponding configuration.
Inserted manually through the MCDU by the flight crew.
Displayed on the MCDU TAKEOFF page.

VREF : Reference speed used for normal final approach.
Equal to 1.23 × VS of CONF FULL.
Displayed on the MCDU APPR page, if landing is planned in CONF FULL (VLS CONF FULL).

VAPP : Final approach speed.
Displayed on MCDU APPR page.
Calculated by the FMGCs.
Represents : VAPP = VLS + wind correction
The wind correction is limited to a minimum of 5 kt and a maximum of 15 kt.

The flight crew may modify VAPP through the MCDU.
- During autoland or when A/THR is on or in case of ice accretion or gusty crosswind greater than 20 kt, VAPP must not be lower than VLS +5 kt.

VAPP TARGET : Represented by a magenta triangle.
Calculated by the FMGCs
Gives efficient speed guidance in approach during various windy conditions.
Represents :
VAPP TARGET = GS mini + actual headwind (measured by ADIRS)
GS mini = VAPP – TOWER WIND (headwind component along runway axis calculated by FMGC from tower wind entered on MCDU).

Intentionally left blank

AIR CONDITIONING

Applicable to: ALL

An external HP source may be used for air conditioning, provided the air supply is confirmed to be free from oil contamination.

Intentionally left blank

AUTOMATIC FMGS RESET AND RESYNCHRONIZATION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FM RESET

When the FM software cannot work properly or receives instructions to perform impossible operations, it automatically resets itself. A resynchronization with the other FM always follows. When the reset is a minor one, the system will recover by itself. One single reset lasts 2 to 3 s maximum followed by 25 s of resynchronization.

When the reset is a major one:
- Resets recur at short intervals (several in 2 or 3 min)
- The memories are cleared, leading to the loss of F-PLN, GW, CI, CRZ FL, MCDU-entered speeds and NAVAIDs and to database switching.

Applicable to: B-HSQ, B-HSR

FM RESET

When the FM software cannot work properly or receives instructions to perform impossible operations, it automatically resets itself. A resynchronization with the other FM always follows. When the reset is a minor one, the system will recover by itself. One single reset lasts 2 to 3 s maximum followed by a resynchronization.

When the reset is a major one:
- Resets recur at short intervals (several in 1 min)
- The memories are cleared, leading to the loss of F-PLN, GW, CI, CRZ FL, MCDU-entered speeds and NAVAIDs.

Note: If four dual FM resets occur in 3 min, pilot-entered data is lost. If a dual reset is identified, it is recommended that the flight crew does not perform again the last MCDU actions for 1 min (in order to avoid a potential second dual reset, leading to the loss of pilot-entered data).

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FM RESYNCHRONIZATION

An FM resynchronization automatically occurs after an FM reset but it may occur independently each time self comparisons between FM1 and FM2 reveal discrepancies.
One single resynchronization lasts approximately 25 s.
If 5 several resynchronizations occur within 5 min, independent mode commences.

Applicable to: B-HSQ, B-HSR

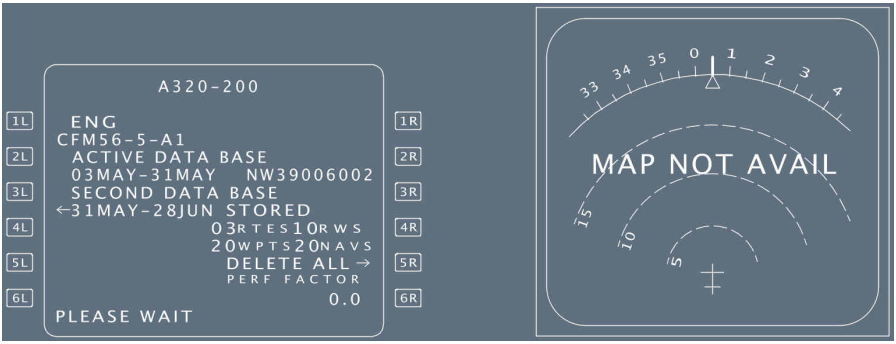
FM RESYNCHRONIZATION

An FM resynchronization automatically occurs after an FM reset. But, it may occur independently each time self-comparisons between the FM1 and FM2 reveal discrepancies.
If three successive resynchronizations fail, independent mode commences.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

FMGC STATUS DURING A RESET/RESYNCHRONIZATION

While a RESET/RESYNCH occurs:
- The ND shows “MAP NOT AVAIL”
- The MCDU reverts to the A/C STATUS page, with “PLEASE WAIT” displayed in the scratchpad
- Autotuning of Navaids (VOR, DME, ADF) are lost on the failed side
- AP and managed modes may be transiently lost (reversion to HDG/V/S or TRK/FPA)
- If the pilot presses a key while the scratchpad is showing “PLEASE WAIT”, there is no change at MCDU level. This is normal, and the crew should no respond by pulling the MCDU circuit breaker.

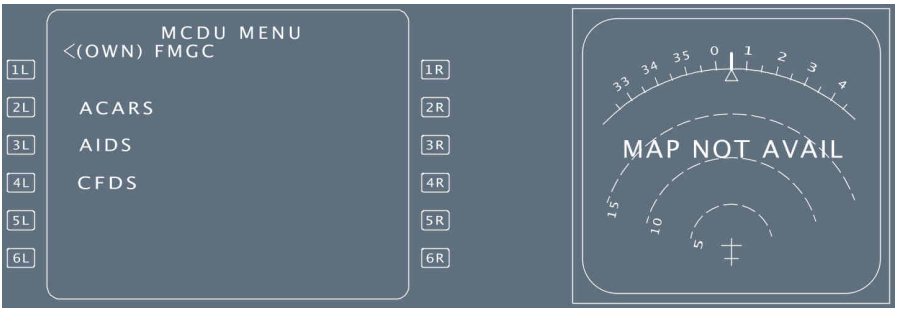


Applicable to: B-HSQ, B-HSR

FMGC STATUS DURING A RESET/RESYNCHRONIZATION

While a RESET/RESYNCH occurs:
- The ND shows “MAP NOT AVAIL”
- The MCDU may revert to the MCDU MENU page
- Autotuning of Navaids (VOR, DME, ADF) are lost on the failed side

- AP/FD /A/THR modes may be transiently lost
- A reversion to basic modes (HDG/V/S or TRK/FPA) occurs if the FM1 (FM2) resets while AP1 (AP2) is engaged.



Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

SINGLE RESET OR DUAL RESET WITH AUTORECOVERY

If the RESET/RESYNCH succeeds, all functions are recovered.

Note: When an FMGC is recovered, its FD if previously engaged, is also recovered and its status is displayed on the FMA.

PROCEDURE

RESELECT the convenient MCDU page.
REENGAGE managed modes and the AP.

WAIT 1 min after the "PLEASE-WAIT" message has disappeared, before engaging the AP/FD of the failed FMGC.

If "MAP NOT AVAIL" remains displayed, along with "SET OFFSIDE RNG/MODE" on one ND, temporarily SELECT a different mode on the corresponding EIS control panel.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

SINGLE RESET OR DUAL RESET WITH AUTORECOVERY

If the RESET/RESYNCH succeeds, all functions are recovered.

Note: When an FMGC is recovered, its FD if previously engaged, is also recovered and its status is displayed on the FMA.

PROCEDURE

RESELECT the convenient MCDU page.

REENGAGE managed modes and the AP.

WAIT 1 min after the "PLEASE-WAIT" message has disappeared, before engaging the AP/FD of the failed FMGC.

If both "MAP NOT AVAIL" and "SET OFFSIDE RNG/MODE" remain displayed on one ND, or if "OFFSIDE FM CONTROL" remains displayed, temporarily SELECT a different mode or range on the corresponding EIS control panel.

Applicable to: B-HSQ, B-HSR

SINGLE RESET OR DUAL RESET WITH AUTORECOVERY

If the RESET/RESYNCH succeeds, all functions are recovered.

Note: *When an FMGC is recovered, its FD if previously engaged, is also recovered and its status is displayed on the FMA.*

PROCEDURE

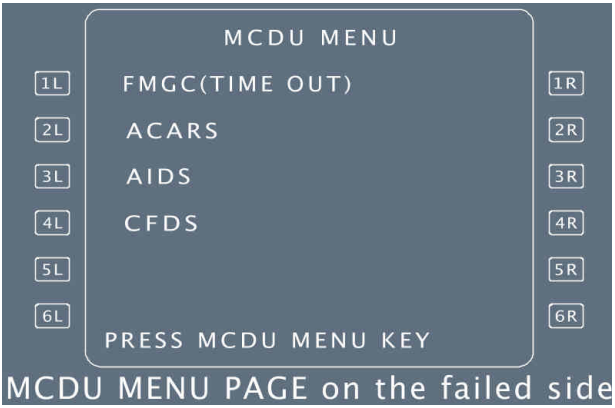
RESELECT the convenient MCDU page.
REENGAGE managed modes, and the AP and A/THR, if necessary.
If both "MAP NOT AVAIL" and "SET OFFSIDE RNG/MODE" remain displayed on one ND, or if "OFFSIDE FM CONTROL" remains displayed, temporarily SELECT a different mode or range on the corresponding EIS control panel.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

SINGLE LATCH

If five successive resets occur, the failing FMGC will latch, and single mode operation will start.

While failed, the following occurs:
- The failed ND side displays "MAP NOT AVAIL" and "SELECT OFFSIDE RNG/MODE" (if the NDs are not both in the same mode or range)
- The MCDU reverts to the MENU PAGE and shows an "FMGC TIME OUT" prompt
- If the AP and FD were previously engaged on the failed side, the AP and FD disengage and the right-hand column of the FMA shows that the operating FD is offside. The ECAM displays the "AP OFF" warning, and the master warning light and audio remind the pilot of the AP disengagement
- All functions are restored on the operative side.



PROCEDURE

Select the same range and mode on both NDs to give the failed ND side something to display.
Select any function key on the affected FMGC MCDU. (The page will display "OPP FMGC IN PROGRESS").

Both MCDUs are now driven by the other FMGC, and only one AP/FD is available. The system works in SINGLE Mode.

Perform a manual reset of the failed FMGC, when convenient.

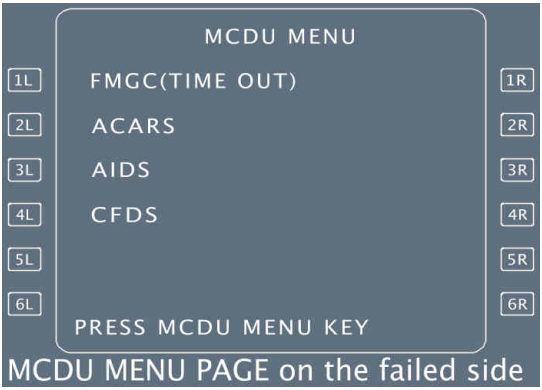
Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

SINGLE LATCH

If five successive resets occur, the failing FMGC will latch, and single mode operation will start.

While failed, the following occurs:

- On the ND usually associated with the failed FMGC:
  If the NDs are not both in the same mode or range, the associated ND displays "MAP NOT AVAIL" and "SET OFFSIDE RNG/MODE". If the NDs are in the same mode and range, the associated ND displays the "OFFSIDE FM CONTROL" amber message
- The MCDU reverts to the MENU PAGE and shows an "FMGC TIME OUT" prompt
- If the AP and FD were previously engaged on the failed side, the AP and FD disengage and the right-hand column of the FMA shows that the operating FD is offside. The ECAM displays the "AP OFF" warning, and the master warning light and audio remind the pilot of the AP disengagement.
- All functions are restored on the operative side.



MCDU MENU PAGE on the failed side

PROCEDURE

Select the same range and mode on both NDs to give the failed ND side something to display.
Select any function key on the affected FMGC MCDU. (The page will display “OPP FMGC IN PROGRESS”).

Both MCDUs are now driven by the other FMGC, and only one AP/FD is available. The system works in SINGLE Mode.

Perform a manual reset of the failed FMGC, when convenient.

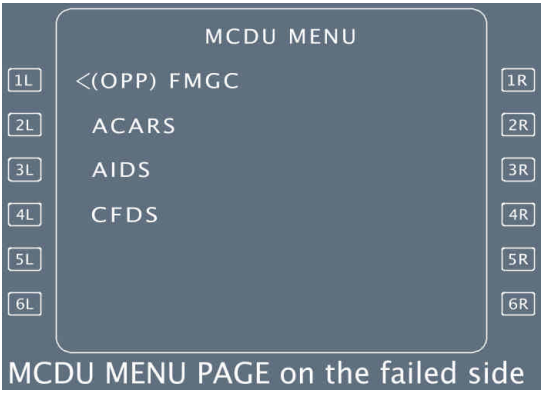
Applicable to: B-HSQ, B-HSR

SINGLE LATCH

If five successive resets occur in 4 min, the failing FMGC will latch, and single mode operation will start.

While failed, the following occurs:

- On the ND usually associated with the failed FMGC:
  If the NDs are not both in the same mode or range, the associated ND displays “MAP NOT AVAIL” and “SET OFFSIDE RNG/MODE”. If the NDs are in the same mode and range, the associated ND displays the “OFFSIDE FM CONTROL” amber message
- The MCDU reverts to the MENU PAGE and shows an “(OPP) FMGC” prompt
- If the AP and FD were previously engaged on the failed side, the AP and FD disengage and the right-hand column of the FMA shows that the operating FD is offside. The ECAM displays the “AP OFF” warning, and the master warning light and audio remind the pilot of the AP disengagement
- All functions are restored on the operative side.



PROCEDURE

Select the same range and mode on both NDs to give the failed ND side something to display.
Select any function key on the affected FMGC MCDU. (The page will display "OPP FMGC IN PROCESS").

Both MCDUs are now driven by the other FMGC, and only one AP/FD is available. The system works in SINGLE Mode.

Perform a manual reset of the failed FMGC, when convenient.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

DUAL RESET WITH LOSS OF DATA AND AUTORECOVERY

Three successive dual resets without result erases all pilot-entered data (F-PLN, GW, CRZ FL, CI...).

When FMGS recovery is obtained:
- Database cycle may have switched
- The FM position bias is lost. The FM position returns to the MIX IRS position
- Autotuning the VOR/DME is restored, based on the aircraft's IRS position
- FMGS tuning of the ILS and ADF is not possible
- Lateral and vertical managed mode cannot reengage
- The "CAB PR LDG ELEV FAULT" ECAM message is displayed
- A map display may be lost on one ND.

PROCEDURE

When the system has recovered:

SELECT the initial database.
SELECT DIR TO the required downpath waypoint.

SELECT LAT REV at the downpath waypoint, and redefine the DESTINATION.
SELECT the FUEL PRED page, and enter GW.
SELECT the PROG page, and enter CRZ FL.
SELECT the PERF page, and enter CI.
CHECK or reengage (as appropriate) the relevant speed/Mach target and vertical mode.

Redefine the flight plan for the remainder of the flight, as the opportunity presents itself.

If "MAP NOT AVAIL" remains displayed, along with "SET OFFSIDE RNG/MODE" on one ND, temporarily SELECT a different mode on the corresponding EFIS control panel.
PERFORM a NAV accuracy check, when possible.

A manual FM position update should be considered, if MIX IRS and actual positions differ by more than 20 nm.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

DUAL RESET WITH LOSS OF DATA AND AUTORECOVERY

Three successive dual resets without result erases all pilot-entered data (F-PLN, GW, CRZ FL, CI...).

When FMGS recovery is obtained:
- Database cycle may have switched
- The FM position bias is lost. The FM position returns to the MIX IRS position
- Autotuning the VOR/DME is restored, based on the aircraft's IRS position
- FMGS tuning of the ILS and ADF is not possible
- Lateral and vertical managed mode cannot reengage
- The "CAB PR LDG ELEV FAULT" ECAM message is displayed
- A map display may be lost on one ND.

PROCEDURE

When the system has recovered:

SELECT the initial database.
SELECT DIR TO the required downpath waypoint.
SELECT LAT REV at the downpath waypoint, and redefine the DESTINATION.
SELECT the FUEL PRED page, and enter GW.
SELECT the PROG page, and enter CRZ FL.
SELECT the PERF page, and enter CI.
CHECK or reengage (as appropriate) the relevant speed/Mach target and vertical mode.

Redefine the flight plan for the remainder of the flight, as the opportunity presents itself.

If both "MAP NOT AVAIL" and "SET OFFSIDE RNG/MODE" remain displayed on one ND, or if "OFFSIDE FM CONTROL" remains displayed, temporarily SELECT a different mode or range on the corresponding EFIS control panel.

PERFORM a NAV accuracy check, when possible.

A manual FM position update should be considered, if MIX IRS and actual positions differ by more than 20 nm.

Applicable to: B-HSQ, B-HSR

DUAL RESET WITH LOSS OF DATA AND AUTORECOVERY

Four successive dual resets in 3 min erases all pilot-entered data (F-PLN, GW, CRZ FL, CI...).

When FMGS recovery is obtained:
- The FM position bias is lost. The FM position returns to the MIX IRS position
- Autotuning the VOR/DME is restored, based on the aircraft's IRS position
- FMGS tuning of the ILS and ADF is not possible
- Lateral and vertical managed mode cannot reengage
- The "CAB PR LDG ELEV FAULT" ECAM message is displayed
- A map display may be lost on one ND.

PROCEDURE

When the system has recovered:

SELECT DIR TO the required downpath waypoint.
SELECT LAT REV at the downpath waypoint and redefine the DESTINATION.
SELECT the FUEL PRED page, and ENTER the ZFW and ZFWCG values.
SELECT the PROG page, and enter CRZ FL.
SELECT the PERF page, and enter CI.
CHECK or reengage (as appropriate) the relevant speed/Mach target and vertical mode.

Redefine the flight plan for the remainder of the flight, as the opportunity presents itself.

If both "MAP NOT AVAIL" and "SET OFFSIDE RNG/MODE" remain displayed on one ND, or if "OFFSIDE FM CONTROL" remains displayed, temporarily SELECT a different mode or range on the corresponding EFIS control panel.
PERFORM a NAV accuracy check, when possible.

A manual FM position update should be considered, if MIX IRS and actual positions differ by more than 20 nm.

Applicable to: B-HSQ, B-HSR

FMS DEGRADED MODE

In some remote cases (several automatic resets in a row on one or both FMS), the affected FMS(s) may enter a "degraded mode", with no predictions.
The intent of this degraded mode is to keep maximum use of the FMS and related functions.

The characteristics of this FMS degraded mode are the following:
- The predictions are lost on the affected FMS(s). All predictions are replaced by dashes on MCDU pages
- The vertical profile and managed speed computations are lost on the affected FM(s) (in Approach phase, VAPP is correctly computed and managed speed is available)
- Managed vertical guidance and managed speed (if previously used) are lost and revert to selected mode
- Lateral path computation and guidance remain available
- The MCDU displays the "FM PREDICTIONS LOST" message.

Note: *1. If predictions are lost on one FMS only, all managed modes are available when using the other side AP.*
2. The Approach phase must be activated manually.

PROCEDURE

● **If the message "FM PREDICTIONS LOST" is displayed:**

- If vertical managed guidance and/or prediction are not deemed necessary, keep using the FMS as needed for Lateral navigation only. Use selected modes for vertical and speed guidance.

  Note: *If only one FMS has entered the degraded mode, consider using the other AP.*

- If vertical managed guidance and/or predictions are required, RE-ENTER a Cost Index (CI) value on INIT A or PERF page (predictions for the active flight plan are then recomputed).

  Note: *In approach phase, a direct CI entry is not allowed : it is then not possible to recover predictions. However, entry of the current altitude in the CRZ FL field will force the CRZ phase and thus, allow to reenter the CI. The approach phase may then be re-activated again.*

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

DUAL LATCH

- Both FMGCs are inoperative. FM and FG capability are lost
- Both NDs display "MAP NOT AVAILABLE". NAVAID tuning is not performed
- AP/FD, A/THR are lost

- FMGC (TIME OUT) subsystem page is displayed on both MCDUs
- The following messages are displayed on the ECAM:
  "CAB PR LDG ELEV FAULT"
  "AUTO FLT AP OFF", if AP was engaged
  "AUTO FLT A/THR OFF", if A/THR was engaged.

PROCEDURE

FLY raw data.
TUNE necessary NAVAIDs using the RMPs.
PERFORM a manual reset of both FMGCs.

Note: *A recovery will result in the loss of all pilot-entered data.*

Note for all FMGS automatic resets

- A single or double FM auto-reset does not affect an ILS approach below 700 ft AGL. ILS frequency is locked and AP/FDs remain engaged
- Above 700 ft , the loss of ILS tuning due to a dual reset will cause a loss of LOC and G/S, and the disengagement of APs and FDs
- During a non ILS approach, if the master FMGC fails, AP/FD and managed modes are lost and FDs engage in basic modes.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

DUAL LATCH

- Both FMGCs are inoperative. FM and FG capability are lost
- Both NDs display "MAP NOT AVAILABLE". NAVAID tuning is not performed
- AP/FD, A/THR are lost
- FMGC (TIME OUT) subsystem page is displayed on both MCDUs
- The following messages are displayed on the ECAM:
  "CAB PR LDG ELEV FAULT"
  "AUTO FLT AP OFF", if AP was engaged
  "AUTO FLT A/THR OFF", if A/THR was engaged.

PROCEDURE

FLY raw data.
TUNE necessary NAVAIDs using the RMPs.
PERFORM a manual reset of both FMGCs.

■ **If successful, refer to dual reset with loss of data and auto recovery:**

Note: *A recovery will result in the loss of all pilot-entered data.*

■ **If unsuccessful:**

FLY raw data.

Select the NAV B/UP prompt on both MCDU DATA pages.

(Refer to DSC-22_20-60-130 General HOW TO USE, concerning navigation backup operation).

SET the landing elevation of the destination on the overhead panel.

Note for all FMGS automatic resets

- A single or double FM auto-reset does not affect an ILS approach below 700 ft AGL. ILS frequency is locked and AP/FDs remain engaged
- Above 700 ft , the loss of ILS tuning due to a dual reset will cause a loss of LOC and G/S, and the disengagement of APs and FDs
- During a non ILS approach, if the master FMGC fails, AP/FD and managed modes are lost and FDs engage in basic modes.

MANUAL FMGS RESET

Applicable to: ALL

On rare occasions, the FMGC may require manual resetting.
If this occurs in flight, reset one FMGC at a time.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

MANUAL RESET OF ONE FMGC

- Before resetting FMGC 1 (or 2), SWITCH OFF FD 1 (or 2)
  After applying external power or APU generator power, wait 2 min before resetting the FMGC circuit breakers
- Pull the CB of the affected FMGC and reset it after 5 s. The FMGC circuit breakers are:
  - AUTO FLT/FMGC 1 B2 ON 49 VU
  - AUTO FLT/FMGC 2 M17 ON 121 VU.

CAUTION	Always wait 1 min after the “PLEASE WAIT” message disappears from the MCDU, before engaging or reengaging the FDs and the AP of the reset FMGC.

Applicable to: B-HSQ, B-HSR

MANUAL RESET OF ONE FMGC

- Before resetting FMGC 1 (or 2), SWITCH OFF FD 1 (or 2)
  After applying external power or APU generator power, wait 2 min before resetting the FMGC circuit breakers
- Pull the CB of the affected FMGC and reset it after 5 s. The FMGC circuit breakers are:
  - AUTO FLT/FMGC 1 B2 ON 49 VU
  - AUTO FLT/FMGC 2 M17 ON 121 VU.

Applicable to: ALL

MANUAL RESET OF BOTH FMGCS

When the aircraft is on ground with the engines stopped, the flight crew may attempt a double and simultaneous CB reset when a single CB reset has failed.
Apply the above-mentioned procedure to both FMGCs.

OTHER ABNORMAL PROCEDURES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

ERRONEOUS PREDICTIONS

The FMGS may display temporary erroneous predictions that can affect such data as ECON speed/Mach, optimum flight level, fuel or time predictions.
If erroneous predictions are observed:

ON GROUND, OR IN FLIGHT

Check the cruise temperature (sign and value), the gross weight, and the cruise flight level.
REENTER the same cost index to restart a computation (In descent or approach, a cost index change does not restart a computation), or
MAKE a COPY ACTIVE, then activate the secondary, or
MAKE a DIR TO the “TO”waypoint.

Applicable to: B-HSQ, B-HSR

ERRONEOUS PREDICTIONS

The FMGS may display temporary erroneous predictions that can affect such data as ECON speed/Mach, optimum flight level, fuel or time predictions.
If erroneous predictions are observed:

ON GROUND, OR IN FLIGHT

Check the cruise temperature (sign and value), the gross weight, and the cruise flight level.
REENTER the same cost index to restart a computation, or
MAKE a COPY ACTIVE, then activate the secondary, or
MAKE a DIR TO the "TO"waypoint.

Applicable to: ALL

SPURIOUS ENGINE OUT INDICATION

If a spurious engine-out is detected:

PROCEDURE

PRESS the EO CLR prompt of the MCDU PERF page
RE-ENGAGE previous vertical mode
RE-ENTER preselected speeds (if any). No other consequences are to be expected.

Applicable to: ALL

"FM/GPS ≪ POS DISAGREE" MESSAGE

This ECAM message is triggered when either one of the FM positions differs from either of the GPS positions by more than 0.5 min of latitude or longitude. This may occur when an update of the FM positions is performed automatically by the FM (Takeoff update or LOC update in approach with unprecise airfield or NAVAID position within the database), or manually by the pilot (manual update). For procedure, Refer to FCOM ABN 34 / NAV FM/GPS POS DISGREE and *Refer to QRH/ABN-34 NAV FM/GPS POS DISAGREE*.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

"CHECK GW"MESSAGE

The "CHECK GW MESSAGE" appears on the MCDU when the Gross Weight (GW) computed by the FMGC and the GW computed by the FAC disagree by more than 7 t (16 055 lb).
When this message appears:

FMS FOB.....CHECK

CALL UP the MCDU FUEL PRED page and compare the FOB to the FOB from the Computerized F-PLN. Correct it if necessary.

FMS GW value.....CHECK

CALL UP the MCDU FUEL PRED page and compare the FMS GW to the GW computed from the loadsheet (ZFW + FOB).

- **If the FMS GW on the MCDU is not correct:**

  FMS GW.....CORRECT/RE-INSERT

  The entry of a correct GW will clear the MCDU message.

- **If the FMS GW on the MCDU is correct:**

  VLS, F, S, GREEN DOT (PFD).....DISREGARD

  If the FMS GW is correct, the characteristic speeds computed by the FAC (displayed on PFD) are not correct.

  QRH OPERATING SPEEDS.....USE

  Refer to QRH/FPE-SPD Speeds

Applicable to: B-HSQ, B-HSR

"CHECK WEIGHT" MESSAGE

The “CHECK WEIGHT” message appears on the MCDU when the Gross Weight (GW) computed by the FMGC and the GW computed by the FAC disagree by more than 7 t (16 055 lb).
When this message appears:

FMS FOB.....CHECK

CALL UP the MCDU FUEL PRED page and compare the FOB to the FOB from the Computerized F-PLN. Correct it if necessary.

FMS ZFW value.....CHECK

CALL UP the MCDU FUEL PRED page and compare the ZFW to the ZFW on the loadsheet (ZFW + FOB).

- **If the FMS ZFW on the MCDU is not correct:**

  FMS ZFW.....CORRECT/RE-INSERT

  The entry of a correct ZFW will clear the MCDU message.

- **If the FMS ZFW on the MCDU is correct:**

  VLS, F, S, GREEN DOT (PFD).....DISREGARD

  If the FMS GW is correct, the characteristic speeds computed by the FAC (displayed on PFD) are not correct.

  QRH OPERATING SPEEDS.....USE

  Refer to QRH/FPE-SPD Speeds

Applicable to: ALL

"AUTO FLT A/THR OFF" MESSAGE

“AUTO FLT A/THR OFF message” may be displayed on the ECAM during cockpit preparation when the FCU A/THR pb has been used on ground to arm and disarm the A/THR. (It is sometimes performed for maintenance purpose).

PROCEDURE BEFORE ENGINE START

ARM the A/THR with the FCU pushbutton to clear the message.
DISARM the A/THR with the instinctive disconnect pushbutton on the thrust levers.

If one engine is started, the FCU pushbutton is inhibited until takeoff and the crew cannot clear the message.

PROCEDURE AFTER ENGINE START

WAIT until takeoff initiation, the warning will automatically disappear when the thrust levers are set to FLX or TOGA.

Note: *If the warning comes up after engine start, envisage an A/THR failure.*

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

MCDU LOCKED OR BLANK

PROCEDURE

- **When one MCDU locks up, or becomes blank, all FMGS functions remain available, but the pilot cannot enter information into the MCDU, and cannot call up any MCDU pages for display:**

  PULL the CB for the locked or blank MCDU, and PUSH it back in after 10 s.

  Note: *During a RESET/RESYNC, if the crew presses a key while the scratchpad is showing "PLEASE WAIT", there is no change at the MCDU level. This is normal, and the pilot should not respond by pulling the MCDU CB.*

- **When both MCDUs are simultaneously locked up, the failure is usually due to an FMGC software anomaly:**

  Pull the FMGC1 CB and push it back in after 10 s. If unsuccessful, reset the FMGC2 CB.

  The FMGC circuit breakers are:
  - AUTO FLT/FMGC 1 B2 ON 49 VU.
  - AUTO FLT/FMGC 2 M17 ON 121 VU.

Applicable to: B-HSQ, B-HSR

MCDU LOCKED OR BLANK

When an MCDU locks up, or becomes blank, all functions of the FMGS remain available. But, the pilot cannot enter information into the MCDU, and cannot call up any MCDU pages for display.

PROCEDURE

PULL the CB for the locked or blank MCDU, and PUSH it back in after 10 s.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

MCDU LOCKED OR BLANK

When an MCDU locks up, or becomes blank, all functions of the FMGS remain available. But, the pilot cannot enter information into the MCDU, and cannot call up any MCDU pages for display.

PROCEDURE

PULL the CB for the locked or blank MCDU, and PUSH it back in after 10 s.

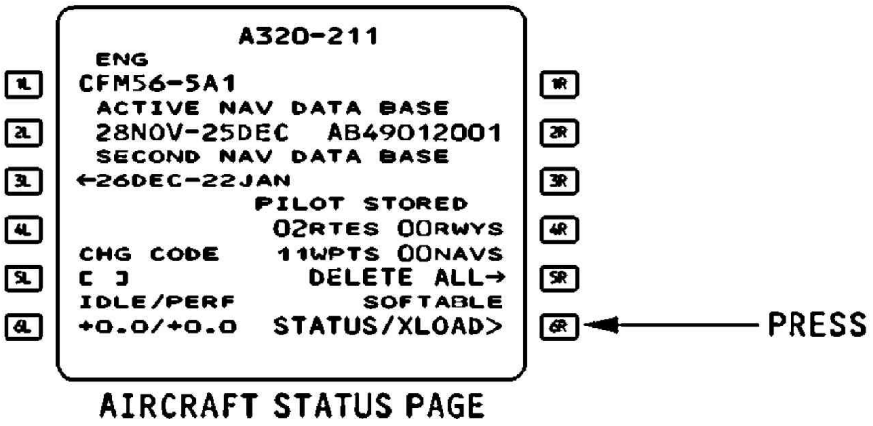
Note: During a RESET/RESYNC, if the crew presses a key while the scratchpad is showing "PLEASE WAIT", there is no change at the MCDU level. This is normal, and the pilot should not respond by pulling the MCDU CB.

Applicable to: B-HSQ, B-HSR

CROSSLOAD OF NAV DATABASE

Both FMGCs are sometimes loaded with 2 different NAV databases. The DUAL mode of operation is not possible until both FMGCs receive the same database. The MCDU displays "FMS1/FMS2 A/C STS DIFF".
This may occur when a spare FMGC is loaded on an aircraft very lately before the flight.
The crossload procedure will be applied to restore the DUAL mode of operations.
CROSSLOAD can be initiated during preflight or done phase only.

CAUTION	The MCDU to be used is the MCDU of the FMGC loaded with the correct NAV database.



AIRCRAFT STATUS PAGE

PROCEDURE

PRESS the “SOFTWARE STATUS/XLOAD” key, on the field [6R].

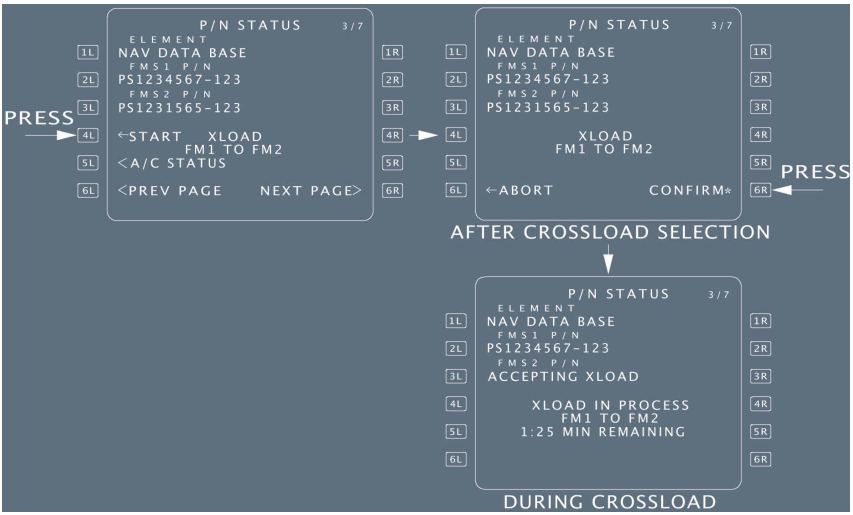
The P/N STATUS page appears.

SELECT “P/N STATUS” page 3.

The navigation database part numbers are displayed.

PRESS “START XLOAD” key, on the field [4L].
PRESS “CONFIRM” key on the field [6R].

Crossloading is initiated and “XLOAD IN PROCESS” is displayed on both MCDUs.



Note: If flight phase transitions from PREFLIGHT or DONE while crossload is in process, the crossload is aborted. If crossload is unsuccessful “CROSSLOAD ABORTED” is displayed on both MCDU’s scratchpad. This message is also displayed following a failed or incomplete data base loader operation.

Upon successful completion of the crossload, “CROSSLOAD COMPLETE” message is displayed on each MCDUs scratchpad. A RESYNCH occurs and both MCDUs return to the AIRCRAFT STATUS page.

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

CROSSLOAD OF NAV DATABASE

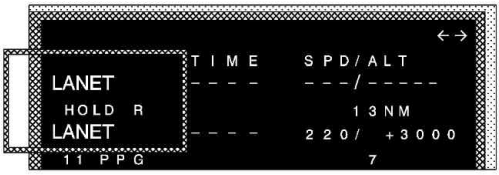
INCORRECT MANAGEMENT OF SPEED CONSTRAINT FOR ARRIVAL PROCEDURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

A procedure Holding Pattern (HOLD) is part of a navigation database procedure. The flight crew cannot manually insert it in the flight plan.
The aircraft flies the HOLD one time, and exits it automatically at the HOLD fix.



Procedure HOLD on the F-PLN MCDU page

The FMS computes procedure HOLDs based on the predicted speed of the aircraft at the pattern entry. For an arrival procedure HOLD, the FMS-predicted speed takes into account:

- The ICAO-fixed speed limit for the hold,
- Any speed constraint coded at the hold entry fix.

Some operators reported the following misbehaviour : if charts indicate a speed constraint for a procedure HOLD, the FMS erroneously applies this speed constraint only at the exit fix, instead of the entry fix. As a consequence, the FMS-predicted HOLD speed does not take the speed constraint into account.
As a result, the FMS may compute the HOLD based on a speed that is higher than required. In such a case, the HOLD will have a size larger than expected.

Note: *If the flight crew reverts to selected speed to reduce the speed at the HOLD entry, the FMS will not re-compute the size of the HOLD.*

OPERATIONAL RECOMMENDATION

During descent preparation :

- Use the charts to CHECK if the arrival procedure includes a HOLD that has a speed constraint.
- If the arrival procedure includes a HOLD that has a speed constraint : ENTER MANUALLY the speed constraint at the hold entry fix.

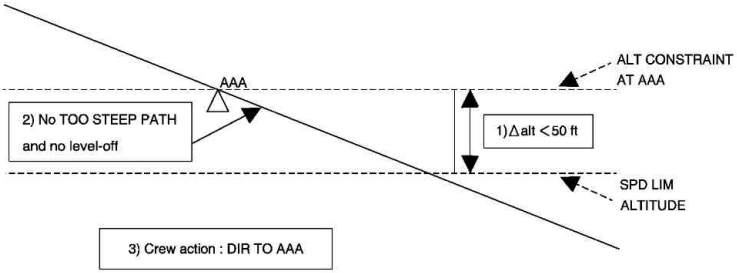
SEVERE RESET WHEN THE DESCENT LIMIT ALT IS CLOSE TO AN ALT CSTR

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

Severe resets with loss of flight plan occur in the following conditions :

1. A waypoint with a descent altitude constraint is located at less than 50 ft from the descent speed limit altitude,
2. This altitude-constrained waypoint is not followed by a too steep path or a level-off,
3. The flight crew performs a DIR TO this altitude-constrained waypoint.

Note: *The altitude constraint on the waypoint may come from the Navigation database coding or from a flight crew's entry.*



As of today, these resets happen systematically in case of DIR TO on several STARs located in Ukraine. The reason is that in this area, procedures often contain by design an altitude constraint that is very close to the speed limit altitude.
Moreover, these resets may also happen anywhere, in cases where the flight crew has manually entered an altitude constraint that is very close to the speed limit altitude.

OPERATIONAL RECOMMENDATION

Do not perform a DIR TO a waypoint that has an altitude constraint located at less than 50 ft from the descent speed limit altitude.

Note: *The pseudo-waypoint "(LIM)" represents the descent speed limit on the F-PLN page.*

ERRONEOUS FUEL PREDICTIONS IN THE CASE OF DESCENT WITH TWO ALTITUDE CONSTRAINTS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

DESCRIPTION

If the flight plan has two altitude constraints for the descent, the flight crew may notice erroneous FMS fuel predictions.

EXPLANATION

If the flight plan has two altitude constraints for the descent, the FMS may define a geometric segment between both altitude constraints. If there is a deceleration required within the geometric segment, the FMS may consider that the geometric segment is too steep to fly without speedbrakes. In this case, the FMS tags the entire geometric segment as a speedbrake segment : The FMS assumes that during the entire segment half of the speedbrakes are extended, even for the parts where no deceleration is planned. As a consequence, the FMS will predict an increased thrust for the entire geometric segment. This may lead to erroneous fuel predictions. (a long geometric segment (e.g. above 100 nm) may lead to an error of 1.5 t for the fuel prediction at destination).

Note: *When flying the geometric segment, the predictions become better as the aircraft approaches the end of the geometric segment, and turn back to normal when the aircraft has sequenced the second altitude constraint.*

PROCEDURE

If the flight crew suspects this behavior in preflight, or during the flight, they can delete and enter again one altitude constraint in descent and compare the fuel predictions of the flight plan with and without the geometric segment. This allows the flight crew to evaluate the impact of the geometric segment on the fuel predictions.
It is not recommended to permanently delete altitude constraints that are stored in the navigation database.

Intentionally left blank

FMS2 Honeywell Specificities

DUAL FMS RESET AFTER A "CLEAR FROM" IN THE F-PLN

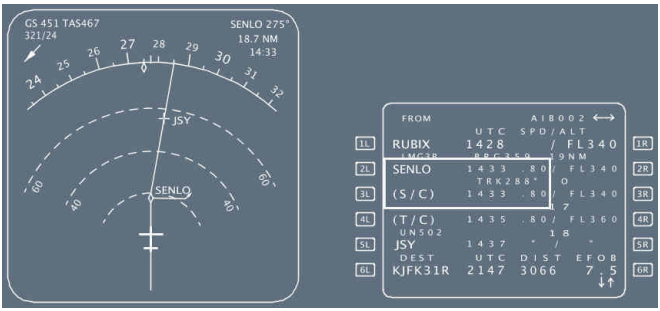
Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

A dual FMS reset, with loss of all pilot-entered data, may occur when the following conditions are met:

- 2 steps (at least) are defined in the active F-PLN, and the first step is defined at the current "TO"waypoint
- The flight crew clears the "FROM" waypoint (or "PPOS") on the active F-PLN (by a CLR action on 1L key on the F-PLN page), to force a F-PLN sequencing.

A step defined at the "TO"waypoint can be identified by the flight crew:

- On the ND : A white climb/descent arrow is displayed next to the "TO"waypoint, or
- On the F-PLN page : The TO waypoint is followed by a Step Climb (S/C), or Step Descent (S/D) pseudo-waypoints in the F-PLN waypoint list.



The reset can occur, in all flight phases, except DESCENT, APPROACH and GO AROUND phases (where no step can be defined).

PROCEDURE

- **If there is a step defined on the current "TO"waypoint of the active F-PLN:**

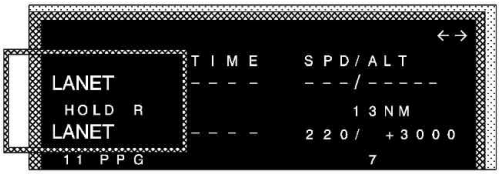
  Do not clear the "FROM" waypoint.

  In order to sequence the F-PLN, the flight crew may either:
  - *Delete the STEP at the "TO"waypoint, prior to clearing the "FROM" waypoint, or*
  - *Perform a "DIR TO"or "DIR TO RADIAL IN", as appropriate.*

INCORRECT MANAGEMENT OF SPD CSTR FOR ARRIVAL PROCEDURE HOLDS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

A procedure Holding Pattern (HOLD) is part of a navigation database procedure. The flight crew cannot manually insert it in the flight plan.
The aircraft flies the HOLD one time, and exits it automatically at the HOLD fix.



Procedure HOLD on the F-PLN MCDU page

The FMS computes procedure HOLDs based on the predicted speed of the aircraft at the pattern entry. For an arrival procedure HOLD, the FMS-predicted speed takes into account:

- The ICAO-fixed speed limit for the hold,
- Any speed constraint coded at the hold entry fix.

Some operators reported the following misbehaviour : if charts indicate a speed constraint for a procedure HOLD, the FMS erroneously applies this speed constraint only at the exit fix, instead of the entry fix. As a consequence, the FMS-predicted HOLD speed does not take the speed constraint into account.
As a result, the FMS may compute the HOLD based on a speed that is higher than required. In such a case, the HOLD will have a size larger than expected.

Note: If the flight crew reverts to selected speed to reduce the speed at the HOLD entry, the FMS will not re-compute the size of the HOLD.

OPERATIONAL RECOMMENDATION

During descent preparation :

- Use the charts to CHECK if the arrival procedure includes a HOLD that has a speed constraint.
- If the arrival procedure includes a HOLD that has a speed constraint : ENTER MANUALLY the speed constraint at the hold entry fix.

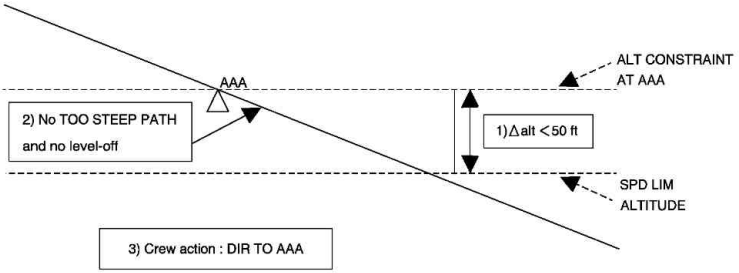
SEVERE RESET WHEN THE DESCENT SPD LIMIT ALT IS CLOSE TO AN ALT CSTR

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

Severe resets with loss of flight plan occur in the following conditions :

1. A waypoint with a descent altitude constraint is located at less than 50 ft from the descent speed limit altitude,
2. This altitude-constrained waypoint is not followed by a too steep path or a level-off,
3. The flight crew performs a DIR TO this altitude-constrained waypoint.

Note: *The altitude constraint on the waypoint may come from the Navigation database coding or from a flight crew's entry.*



As of today, these resets happen systematically in case of DIR TO on several STARs located in Ukraine. The reason is that in this area, procedures often contain by design an altitude constraint that is very close to the speed limit altitude.
Moreover, these resets may also happen anywhere, in cases where the flight crew has manually entered an altitude constraint that is very close to the speed limit altitude.

OPERATIONAL RECOMMENDATION

Do not perform a DIR TO a waypoint that has an altitude constraint located at less than 50 ft from the descent speed limit altitude.

Note: *The pseudo-waypoint "(LIM)" represents the descent speed limit on the F-PLN page.*

LOSS OF PREDICTIONS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

A loss of FMS predictions may be encountered upon the following conditions :

- The Flight Plan (F-PLN) contains an ILS approach
- There is an AT or ABOVE altitude constraint at a waypoint before the Final Approach Fix (FAF)
- The flight crew modifies the AT or ABOVE constraint into an AT altitude constraint.

In such a case, the FMS prediction algorithm may not succeed to compute the predictions, depending on A/C type, A/C weight and ILS approach geometry. This is not systematic and this is related to the performance of the A/C (GW, geometric conditions).

PROCEDURE

- REENTER the AT or ABOVE constraint to launch new predictions computation.

LOSS OF FMS POSITION FURTHER TO IRS LOSS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

The loss or the failure of an Inertial Reference System (IRS) could result in the loss of the FMS position with the following cockpit effects :

- MAP NOT AVAIL GPS, PRIMARY LOST displayed on ND
- The DIR TO page is unavailable on both MCDU
- During approach, transient ATHR thrust variations at autopilot disconnection (Only applicable in case of IR 1 FAULT).

Technical explanation :
The FMS needs valid data from the IRS in order to compute a position.
The FMS checks the IRS data with a specific parameter coming from the Flight Guidance (FG) part of the FMGC. When an IRS is lost or off (dispatched inoperative), the onside FG erroneously indicates to the FMS that the IRS DATA is still valid.
As a result, the FMS position is lost on the same side than the IRS inoperative (IRS1 for FMS1 and IRS for FMS2). The manual switching on IRS 3 (ATT HDG on CAPT 3 or F/O 3) does not enable to recover the data.

PROCEDURE:

In case of an IR x FAULT ECAM warning in flight with the above mentioned cockpit effects, apply the following procedure :
De-activate (do not perform a reset) the FMS on the same side than the IRS inoperative :

- For IR 1 FAULT : pull FMGC 1 CB B2 (VU 49)
- For IR 2 FAULT : pull FMGC 2 CB M17 (VU 121)

ERRONEOUS FUEL PREDICTION IN THE CASE OF DESCENT WITH TWO ALTITUDE CONSTRAINTS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

DESCRIPTION:

If the flight plan has two altitude constraints for the descent, the flight crew may notice erroneous FMS fuel predictions.

EXPLANATION

If the flight plan has two altitude constraints for the descent, the FMS may define a geometric segment between both altitude constraints. If there is a deceleration required within the geometric segment, the FMS may consider that the geometric segment is too steep to fly without speedbrakes. In this case, the FMS tags the entire geometric segment as a speedbrake segment : The FMS assumes that during the entire segment half of the speedbrakes are extended, even for the parts where no deceleration is planned. As a consequence, the FMS will predict an increased thrust for the entire geometric segment. This may lead to erroneous fuel predictions. (a long geometric segment (e.g. above 100 nm) may lead to an error of 1.5 t for the fuel prediction at destination).

Note: *When flying the geometric segment, the predictions become better as the aircraft approaches the end of the geometric segment, and turn back to normal when the aircraft has sequenced the second altitude constraint.*

PROCEDURE:

If the flight crew suspects this behavior in preflight, or during the flight, they can delete and enter again one altitude constraint in descent and compare the fuel predictions of the flight plan with and without the geometric segment. This allows the flight crew to evaluate the impact of the geometric segment on the fuel predictions.
It is not recommended to permanently delete altitude constraints that are stored in the navigation database.

UNEXPECTED SWITCH OF SPEED TARGET WHEN RTA IS USED

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

An anomaly could be experienced when the RTA (Requested Time of Arrival) function is used.
The MCDU and the PFD could suddenly display an erroneous speed target at the transition altitude when a RTA is entered and if the flight crew performs an action (Vapp entry or altitude constraint modification) that causes a F-PLN profile recomputation.
This scenario could also occur if the flight crew has inserted a RTA and then deleted this RTA (the FMS may erroneously retain the RTA target).
Some cases could happen while the aircraft is in descent (DES mode) in managed speed. This speed target change is significant at high altitude if the RTA speed target is lower than the speed target used before the beginning of the descent.

PROCEDURE

If an erroneous speed target is displayed at high altitude, the flight crew can manually select a speed to continue the descent.

EOSID F-PLN LIMITED TO 10 LEGS

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

When the EOSID contains more than 10 legs :

- The ND Display in PLAN mode only shows the first 10 legs of the EOSID.
- In the case an engine out occurs before the diversion point, the TMPY flight plan ends at the end of the 10th leg.

To avoid that the EOSID ends after the 10th leg, the flight crew must insert the EOSID as a SID in the secondary flight plan (SEC F-PLN).

PROCEDURE

During Cockpit Preparation :

- CREATE a SEC F-PLN (e.g. using COPY ACTIVE)
- SELECT the EOSID as a SID in the SEC F-PLN.
- REVIEW the display on the ND of the SID for Engine Out (white line) as SEC F-PLN.

In the case of engine failure before the Engine Out Diversion Point :

- ACTIVATE the SEC F-PLN (EOSID)
  If the Navigation Database has not been changed, the automatic proposal of Temporary F-PLN for EOSID must be erased before activating the SEC F-PLN.

Note: To avoid that the flight crew needs to reject the automatic proposed TMPY F-PLN (EOSID limited to 10 legs) in case of engine failure, Airbus recommends that the EOSID is coded in the Navigation Database as a SID and not as an EOSID.

FMS2 Thales/GE Specificities

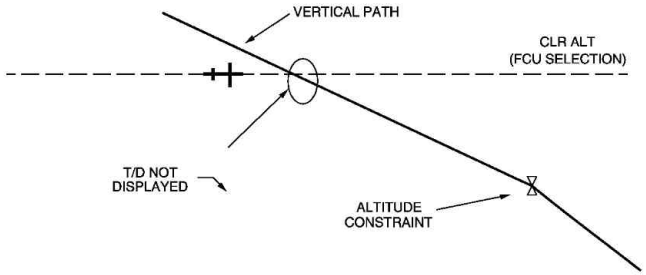
INTERMEDIATE TOP OF DESCENT (T/D) SYMBOL MISSING ON ND DURING DESCENT OR APPROACH PHASES

Applicable to: B-HSQ, B-HSR

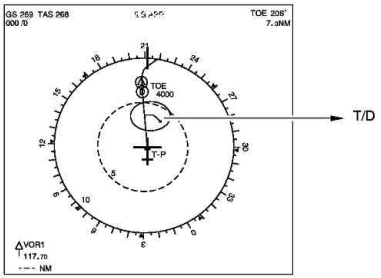
The Top of Descent (T/D) is a position that the system calculates assuming that the aircraft will follow the descent profile computed with all the vertical flight plan (F-PLN) constraints (ALT or SPD CSTR). The T/D symbol is displayed on the ND at the top of descent from CRZ altitude.
The same symbol may then be displayed during descent and approach following an intermediate level-off, e.g. due to ATC request. In such a case, the symbol indicates the point at which the descent should be resumed to follow the vertical profile.
Due to an internal software error of the current S5 FMS Standard, this intermediate T/D symbol will not be displayed on ND when the following conditions apply :

- Aircraft already in Descent or Approach phase
- Aircraft below the F-PLN vertical profile
- Aircraft in ALT mode (altitude selected through the FCU)
- Selected altitude is different from the following F-PLN ALT CSTR.

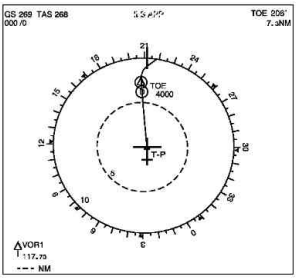
The following graph illustrates the conditions when the anomaly can appear.



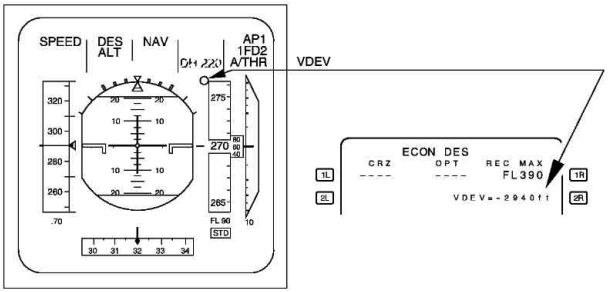
When the conditions apply, the T/D symbol should appear on the ND as follows :



With the current S5 FMS standard, the T/D symbol does not appear, as follows :



Note that with the current S5 FMS Standard affected by this anomaly, the vertical deviation (V/DEV) remains still valid and correct on the PFD and on the MCDU PROG page :

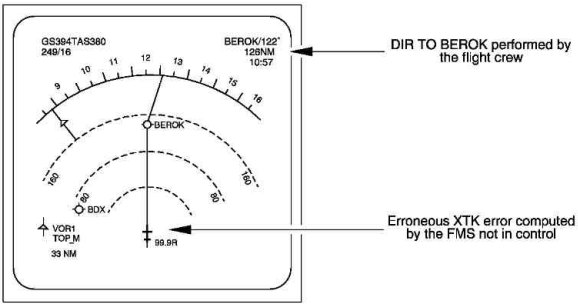


ERRONEOUS CROSS TRACK ERROR/FD DISPLAY ORDERS AFTER A DIR TO ON ALIGNED WAYPOINT

Applicable to: B-HSQ, B-HSR

Erroneous cross track errors (XTK) and FD orders fluctuations have been reported when a DIR TO is performed to a waypoint ahead, with no heading change. In these conditions, some time after the DIR TO, the FMS not in control ("slave FMS") may compute an erroneous XTK using as the reference the next leg after the DIR TO waypoint (the corresponding FD order being based on this erroneous cross track). However, the XTK and FD of the FMS in control remain correct. If later, the flight crew switches the autopilot to the affected FMS side, the aircraft guidance will become erroneous.

Note: If the XTK value (computed by the FMS not in control) is above 128 nm, the XTK and associated FD orders are not displayed



PROCEDURE:

- PERFORM a new DIR TO to recover a correct XTK/FD behaviour.

ERRONEOUS OFFSET

Applicable to: B-HSQ, B-HSR

In some cases, the FMS does not compute correctly the offset path when the flight crew enters an offset in the flight plan. In such case, the offset path does not remain parallel to the parent path, but diverges at a certain point. After the point at which this erroneous diversion starts, the offset path is very different from the intended parallel path and the flight crew must therefore not follow this diverging path.

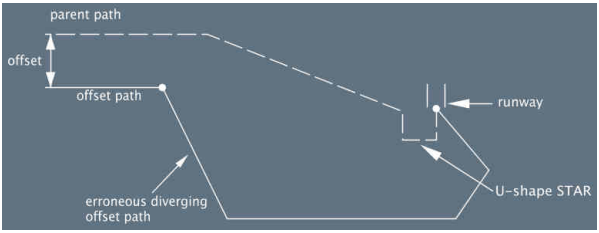
The Estimated Fuel On Board (EFOB) will also be erroneous, because the EFOB computation will be based on this erroneous (and often longer) offset path. When the offset is cancelled, the EFOB becomes again correct.

This anomaly can occur when the flight plan contains a succession of legs with important change in course (e.g. U-Shape, Step-shape,...). These shapes are mainly found in STARs and VIAs. However, the point at which the diversion start may be well before this U-shape/Step-shape (e.g. 100 nm).

Note: *For a given flight plan, the correctness of the offset path depends on the value of offset :*

- *with a smaller offset value, the FMS computes a correct offset path ;*
- *with a bigger offset value the FMS computes an erroneous offset path.*

FIGURE:



PROCEDURE:

When the offset trajectory becomes unsatisfactory, the flight crew should cancel the offset in the FMS. If the offset is still needed, the flight crew can fly the offset in lateral selected guidance.

ERRONEOUS FUEL PREDICTIONS IN THE CASE OF DESCENT WITH TWO ALTITUDE CONSTRAINTS

Applicable to: B-HSQ, B-HSR

DESCRIPTION:

If the flight plan has two altitude constraints for the descent, the flight crew may notice erroneous FMS fuel predictions.

EXPLANATION:

If the flight plan has two altitude constraints for the descent, the FMS may define a geometric segment between both altitude constraints. If there is a deceleration required within the geometric segment, the FMS may consider that the geometric segment is too steep to fly without speedbrakes. In this case, the FMS tags the entire geometric segment as a speedbrake segment : The FMS assumes that during the entire segment half of the speedbrakes are extended, even for the parts where no deceleration is planned. As a consequence, the FMS will predict an increased thrust for the entire geometric segment. This may lead to erroneous fuel predictions. (a long

geometric segment (e.g. above 100 nm) may lead to an error of 1.5 t for the fuel prediction at destination).

Note: *When flying the geometric segment, the predictions become better as the aircraft approaches the end of the geometric segment, and turn back to normal when the aircraft has sequenced the second altitude constraint.*

PROCEDURE:

If the flight crew suspects this behavior in preflight, or during the flight, they can delete and enter again one altitude constraint in descent and compare the fuel predictions of the flight plan with and without the geometric segment. This allows the flight crew to evaluate the impact of the geometric segment on the fuel predictions. It is not recommended to permanently delete altitude constraints that are stored in the navigation database.

"FM PREDICTIONS LOST" MESSAGE WHEN USING THE FUEL PLANNING FUNCTION

Applicable to: B-HSQ, B-HSR

In some cases, in particular when several altitude steps have been entered in the F-PLN, the FUEL PLANNING function may be unable to compute the required BLOCK fuel. When this happens, the system stops computing the predictions and the "FM PREDICTIONS LOST" amber message appears in the scratchpad.

PROCEDURE

- **If the "FM PREDICTIONS LOST" message appears after using the FUEL PLANNING function:**

  DO NOT RE-USE the FUEL PLANNING function

  ENTER the planned BLOCK fuel in the [2R] field on INIT B page

  RE-ENTER the Cost Index (CI) on INIT A page.

  This will re-start the computation of the FMS predictions.

Intentionally left blank

VHF, HF UTILIZATION

Applicable to: ALL

Note: 1. Reception of some frequencies could be noisy, on one or more VHFs. In such cases, try selecting an unaffected one.
2. If two frequencies are closer than 2 MHz (between VHF1 and 2, or between VHF3 and 2), or closer than 6 MHz (between VHF1 and 3), some interference may occur.

Applicable to: B-HSQ, B-HSR

TUNING

The pilot should normally use his onside RMP to tune any one of the VHF or HF radios. If the SEL lights come on, when tuning the radio, the pilot should turn them off by selecting the appropriate radio system dedicated to his RMP.

ON/OFF switch..... CHECK ON
VHF or HF key..... PRESS

The green light comes on.
ACTIVE and STBY/CRS windows display active and preset frequencies, respectively.

Note: When an RMP tunes a transceiver that is normally associated with another RMP, the SEL lights on both RMPs come on.

TO CHANGE FREQUENCY

Rotating knob..... TURN
Make the STBY/CRS window display the new frequency.
Outer knob is for units, inner knob for decimals.

Transfer key..... PRESS
This interchanges the ACTIVE and STBY frequencies.
The receiver is now tuned to the new ACTIVE frequency.

AM key (if necessary)..... PRESS
Green light comes on.

SEL lt..... CHECK OFF

If SEL light is on, select the appropriate radio systems dedicated to the on side RMP.

FAILURE CASES

When an RMP fails :

- The affected RMP no longer controls the selected receiver.
- The frequency displays disappear and the green VHF or HF lights go out.

Affected RMP..... SWITCH OFF

One RMP can control all receivers.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

TUNING

The pilot should normally use his onside RMP to tune any one of the VHF or HF radios. If the SEL lights come on, when tuning the radio, the pilot should turn them off by selecting the appropriate radio system dedicated to his RMP.

ON/OFF switch..... CHECK ON
VHF or HF key..... PRESS

The green light comes on.
ACTIVE and STBY/CRS windows display active and preset frequencies, respectively.

Note: When an RMP tunes a transceiver that is normally associated with another RMP, the SEL lights on both RMPs come on.

TO CHANGE FREQUENCY

Rotating knob..... TURN

Make the STBY/CRS window display the new frequency.
Outer knob is for units, inner knob for decimals.

Transfer key..... PRESS

This interchanges the ACTIVE and STBY frequencies.

The receiver is now tuned to the new ACTIVE frequency.

AM key (if necessary).....PRESS

Green light comes on.

SEL lt..... CHECK OFF

If SEL light is on, select the appropriate radio systems dedicated to the on side RMP.

FAILURE CASES

When an RMP fails :

- The affected RMP no longer controls the selected receiver.
- The frequency displays disappear and the green VHF or HF lights go out.

Affected RMP..... SWITCH OFF

One RMP can control all receivers.

- *if RMP 1 fails tune VHF 1 through RMP 3*
- *if RMP 2 fails tune VHF 2 through RMP 3*
- *if RMP 3 fails tune, HF 1 ◁ through RMP 1, HF 2 ◁ through RMP 2*
- *if two RMP's fail, tune all receivers through the remaining RMP.*

Applicable to: B-HSQ, B-HSR

TRANSMISSION AND RECEPTION

Note: *If the VHF3 VOICE DIRECTORY page is customized with user frequencies:*

- *Use it as a pure directory*
- *Do not press the key adjacent to the desired frequency for direct turning*
- *VHF3 in VOICE mode should either be tuned using the MANUAL FREQ field, or using the RMP.*

VHF or HF transmission key.....PRESS

Green bars on the selected system key light up.

Microphones and PTT command are connected to the selected system.

VHF or HF reception key..... PRESS

The integrated white light comes on.
The receiver brings in the selected system.
To adjust the volume, turn the key.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

TRANSMISSION AND RECEPTION

Note: If the VHF3 VOICE DIRECTORY page is customized with user frequencies:
- *Use it as a pure directory*
- *Do not press the key adjacent to the desired frequency for direct turning*
- *VHF3 in VOICE mode should either be tuned using the MANUAL FREQ field, or using the RMP.*

VHF or HF transmission key..... PRESS

Green bars on the selected system key light up.
Microphones and PTT command are connected to the selected system.

VHF or HF reception key..... PRESS

The integrated white light comes on.
The receiver brings in the selected system.
To adjust the volume, turn the key.

Note: Do not use VHF 3 for communications with ATC, if ACARS is installed, unless VHF 1 and VHF 2 are inoperative.

CAPT- ATT CALL

Applicable to: ALL

PROCEDURE FOR CALLING ATT STATION WHEN PREVIOUS CALL HAS NOT BEEN RESET

If, after a call from cockpit to the attendant's station, the attendant does not press the RESET key on the attendant's panel, the pilot must use the following procedure to call the station :

CAB transmission key (on audio control panel)..... PRESS

Green lines light up.

INT/RAD (on ACP)..... MAINTAIN IN RAD POSITION for 2 s.

Wait 60 s for automatic cancellation of previous CAPT-ATT calls, then :

CAB transmission key..... PRESS

Note: This procedure will no longer be necessary after the introduction of CIDS Mark II standard, which includes a function to reset the system automatically after 60 s if no one has pressed the RESET key.

FROZEN RMP

Applicable to: ALL

A frozen RMP can be evidenced by the impossibility to interchange the ACTIVE and STBY radio navigation or communication frequencies.
In order to recover the normal operation of the RMP, all the RMP's have to be reset, as the problem on one RMP can be due to an other RMP.

PROCEDURE

All the RMP's have to be resetted, one after the other.

- **On the RMP control panel :**

  ON/OFF switch.....OFF

  Wait 5 s then.

  ON/OFF switch.....ON

Intentionally left blank

TRIPPED C/B REENGAGEMENT

Applicable to: ALL

In flight, do not reengage a circuit breaker (C/B) that has tripped by itself, unless the Captain judges it necessary to do so for the safe continuation of the flight. This procedure should be adopted only as a last resort, and only one reengagement should be attempted.
On ground, do not reengage the C/B of the fuel pump(s) of any tank. For all other C/Bs, if the flight crew coordinates the action with maintenance, the flight crew may reengage a tripped C/B, provided that the cause of the tripped C/B is identified.
Refer to Part A 8.3.14.1 for circuit breaker reset policy.

COMPUTER RESET

Applicable to: ALL

The normal purpose of a circuit breaker (C/B) is to protect wiring against short circuits, and to isolate equipment for maintenance.
Another C/B function involves digital computers : The reset function. When a digital computer behaves abnormally due to an electrical transient, for example, the abnormal behavior can be stopped by briefly interrupting the power supply to its processor.
The flight crew can reset most of this aircraft's computers with a normal cockpit control (selector or pushbutton). However, for some systems, the only way to cut off electrical power is to pull the associated C/B.

PROCEDURE

To perform a computer reset:
- Set the related normal cockpit control to OFF, or pull the corresponding circuit breaker
- Wait 3 s if a normal cockpit control is used, or 5 s if a circuit breaker is used (unless a different time is indicated)
- Set the related normal cockpit control to ON, or push the corresponding circuit breaker
- Wait 3 s for the end of the reset.

WARNING	Do not reset more than one computer at the same time, unless instructed to do so.

Note: *In flight, before taking any action on the cockpit C/Bs, both the PF and PNF must:*
- *Consider and fully understand the consequences of taking action*
- *Crosscheck and ensure that the C/B label corresponds to the affected system.*

COMPUTER RESET TABLE

Applicable to: ALL

The computers that are most prone to reset are listed in the table of the next pages with the associated reset procedure, or FCOM reference when applicable.
Specific reset procedures, included in OEB or Temporary revisions, are normally not referenced in this table and, when issued, superseed this table.

Note: *Repetitive resets have to be reported to maintenance.*

- On ground, almost all computers can be reset, and are not limited to the ones indicated in the table.

  Following computers are not allowed to be reset in all circumstances:
  - ECU (Engine Control Unit on CFM engines) or EEC (Electronic Engine Control on IAE engines) and EIU (Engine Interface Unit) while the engine is running.
  - BSCU (Brake Steering Control Unit) if the aircraft is not stopped. (*Refer to PRO-SUP-32 BSCU Reset - On Ground*).

- In flight, as a general rule, the crew must restrict computer resets to those listed in the table, or to those in applicable TRs or OEBs. Before taking any action on other computer the flight crew must consider and fully understand the consequences.

CAUTION	Do not pull the following circuit breakers: - SFCC (could lead to SLATS/FLAPS locked) - ECU or EEC, EIU.

Note: *In the table's "reset" column, the "if applicable" note signifies that, depending on the computer standard, the reset procedure may no longer be necessary. If this is the case, the reset procedure is removed from the applicable FCOM section.*

Intentionally left blank

GENERAL

Applicable to: ALL

The secured cockpit door operation is controlled by a toggle sw, located on the COCKPIT DOOR central pedestal.

DOOR OPENING FROM THE COCKPIT

To allow access the cockpit, the COCKPIT DOOR has to be pulled and maintained in the UNLOCK position until the door is fully opened (once the door is fully opened it can be released to the NORM position).

DOOR CLOSING

Close the door and check that the OPEN indicator goes off. If the toggle sw is in the NORM position the door is locked and emergency access is possible for the cabin crew. If the toggle sw is in the LOCK position the door is locked and the emergency access, the buzzer and the keypad are inhibited for a preselected time (5 to 20 min).

Note: If the OPEN indicator is on with the door closed, the door may be unlocked. Repeat the above opening/closing sequence.

COCKPIT DOOR OPERATION

Applicable to: ALL

GENERAL

The cockpit door should be closed and locked immediately following the report from the FA1 that all passengers are on board and aircraft door closed. Except for crew entry/exit, the cockpit door should remain closed and locked until engine shutdown. Refer to Volume 7.1.15.7 Flight Deck Security.

Applicable to: ALL

BEFORE PUSHBACK OR ENGINE START

COCKPIT DOOR..... CLOSE

With the cockpit door selector at NORM, the cockpit door is closed and locked.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

AFTER ENGINE START

- **If ROUTINE ACCESS is requested from the cabin:**
  The buzzer sounds in the cockpit for 1 to 9 s (3 s by default).

  CAMERA 1 DISPLAY ON CDSS..... CHECK

CAMERA 2 DISPLAY ON CDSS..... CHECK
CAMERA 3 DISPLAY ON CDSS..... CHECK

Prior to unlocking the door, the flight crew should identify the person requesting entry.

- **If entry is NOT authorized by the flight crew:**
  COCKPIT DOOR sw ..... LOCK

- **If entry is authorized by the flight crew:**
  COCKPIT DOOR sw ..... UNLOCK

  Note: If the flight crew does not take any action after a routine cabin request, the cabin crew will be able to open the door by using the emergency access procedure.

- **If EMERGENCY ACCESS is initiated from the cabin:**
  The buzzer will sound continuously in the cockpit, and the OPEN light flashes on the center pedestal's cockpit door panel.

  Note: If the flight crew does not take any action, the door will unlock after a preselected time between 15 and 120 s.

COCKPIT DOOR sw ..... LOCK
CAMERA 1 DISPLAY ON CDSS..... CHECK
CAMERA 2 DISPLAY ON CDSS..... CHECK
CAMERA 3 DISPLAY ON CDSS..... CHECK

Prior to unlocking the door, the flight crew should identify the person requesting entry.

- **If entry is authorized by the flight crew:**
  COCKPIT DOOR sw ..... UNLOCK

Applicable to: B-HSQ, B-HSR

AFTER ENGINE START

- **If ROUTINE ACCESS is requested from the cabin :**
  The buzzer sounds in the cockpit for 1 to 9 s (3 s by default).

CAMERA 1 DISPLAY..... CHECK

Camera 1 is automatically displayed upon entry request.

VIDEO CAMERA pushbutton..... PRESS
CAMERA 2 and 3 DISPLAY..... CHECK

Prior to unlocking the door, the flight crew should identify the person requesting entry.

- **If entry is NOT authorized by the flight crew:**
  COCKPIT DOOR sw ..... LOCK

- **If entry is authorized by the flight crew:**
  COCKPIT DOOR sw ..... UNLOCK

Note: *If the flight crew does not take any action after a routine cabin request, the cabin crew will be able to open the door by using the emergency access procedure.*

- **If EMERGENCY ACCESS is initiated from the cabin:**
  The buzzer will sound continuously in the cockpit, and the OPEN light flashes on the center pedestal's cockpit door panel.

  Note: *If the flight crew does not take any action, the door will unlock after a preselected time between 15 and 120 s.*

  COCKPIT DOOR sw ..... LOCK
  CAMERA 1 DISPLAY ..... CHECK

  Camera 1 is automatically displayed upon entry request.

  VIDEO CAMERA pushbutton ..... PRESS
  CAMERA 2 and 3 DISPLAY ..... CHECK

  Prior to unlocking the door, the flight crew should identify the person requesting entry.

  - **If entry is authorized by the flight crew:**
    COCKPIT DOOR sw ..... UNLOCK

Applicable to: B-HSO, B-HSP

AFTER ENGINE START

- **If ROUTINE ACCESS is requested from the cabin:**
  The buzzer sounds in the cockpit for 1 to 9 s (3 s by default).

  VIDEO LWR ECAM rotary selector ..... CKPT ENTRY
  CAMERA 1 DISPLAY ..... CHECK

  Camera 1 is automatically displayed (on the lower ECAM display) upon entry request.

  VIDEO CAMERA SEL pb ..... PRESS
  CAMERA 2 and 3 DISPLAY ..... CHECK

  Prior to unlocking the door, the flight crew should identify the person requesting entry.

  - **If entry is NOT authorized by the flight crew:**
    COCKPIT DOOR sw ..... LOCK

  - **If entry is authorized by the flight crew:**
    COCKPIT DOOR sw ..... UNLOCK
    VIDEO LWR ECAM rotary selector ..... OFF

    Note: *If the flight crew does not take any action after a routine cabin request, the cabin crew will be able to open the door by using the emergency access procedure.*

● **If EMERGENCY ACCESS is initiated from the cabin:**

The buzzer will sound continuously in the cockpit, and the OPEN light flashes on the center pedestal's cockpit door panel.

Note: If the flight crew does not take any action, the door will unlock after a preselected time between 15 and 120 s.

COCKPIT DOOR sw ..... LOCK
VIDEO LWR ECAM rotary selector ..... CKPT ENTRY
CAMERA 1 DISPLAY..... CHECK

Camera 1 is automatically displayed (on the lower ECAM display) upon entry request.

VIDEO CAMERA SEL pb..... PRESS
CAMERA 2 and 3 DISPLAY..... CHECK

Prior to unlocking the door, the flight crew should identify the person requesting entry.

● **If entry is authorized by the flight crew:**

COCKPIT DOOR toggle switch..... UNLOCK
VIDEO LWR ECAM rotary selector ..... OFF

OPENING THE COCKPIT DOOR FROM THE CABIN - CABIN CREW ROUTINE ACCESS

Applicable to: ALL

CABIN CREW ROUTINE ACCESS..... REQUEST ON KEYPAD
CABIN CREW..... PRESS #, or N+#

"N"represents an Operator-defined figure between 0 and 7 digits.

CABIN CREW..... STAND IN COCKPIT DOOR AXIS

The cabin crew should stand in the axis of the CKPT door. A buzzer sounds in the CKPT.

● **If entry is NOT authorized by the flight crew:**

- The flight crew locks the door via the COCKPIT DOOR sw (LOCK position).
- The keypad's red light comes on steady, and indicates that the door is locked.

● **If entry is authorized by the flight crew:**

- The flight crew unlocks the door via the COCKPIT DOOR sw (UNLOCK position).
- The keypad's green light comes on steady, and indicates that the door is unlocked.

CABIN CREW..... PUSH DOOR TO OPEN

● **If there is no reaction from the flight crew:**

CABIN CREW SECOND ACCESS..... REQUEST ON KEYPAD

Repeat the above procedure.

- **If there is no reaction from the flight crew, after a second request:**
  CABIN CREW.....CALL THE COCKPIT
  To establish contact with the flight crew and request access to the cockpit.

- **If there is no reaction from the flight crew, after a cabin crew interphone call:**
  CABIN CREW..... APPLY THE FOLLOWING EMERGENCY ACCESS PROCEDURE
  EMERGENCY ENTRY CODE.....ENTER and PRESS #
  The emergency entry code is an Operator-defined figure between 2 and 7 digits. A buzzer will sound continuously in the cockpit and the keypad's green light flashes. After a preselected time between 15 s and 120 s, the keypad's green light comes on steady, and the cabin crew can then push the door open.
  CABIN CREW.....PUSH DOOR TO OPEN
  The cockpit door unlocks for 5 s.
  The buzzer stops and indicates that the door is unlocked.

ISOLATION OF AIRWORKS CDSS MONITOR

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Overheating of a component in the Airworks CDSS monitor may result in smoke and a burning smell in the cockpit.
Should smoke and/or a burning smell be experienced in the cockpit and the source is identified as the Airworks CDSS monitor, it is recommended that power be removed from the system as follows:

CDSS pb-sw .....OFF

Intentionally left blank

GENERAL

Applicable to: ALL

The fly-by-wire system has been designed and certificated to make the new generation of aircraft more cost effective and safer and smoother to fly or ride in than a conventional aircraft.

Intentionally left blank

GENERAL

Applicable to: ALL

The pilot uses the sidestick to fly the aircraft in pitch and roll (and indirectly, through turn coordination, in yaw).
The computers interpret the pilot's inputs and move the control surfaces as necessary.

However, regardless of the pilot's inputs the computers will prevent :
- excessive load factor
- loss of control leading to excursions outside the safe flight envelope.

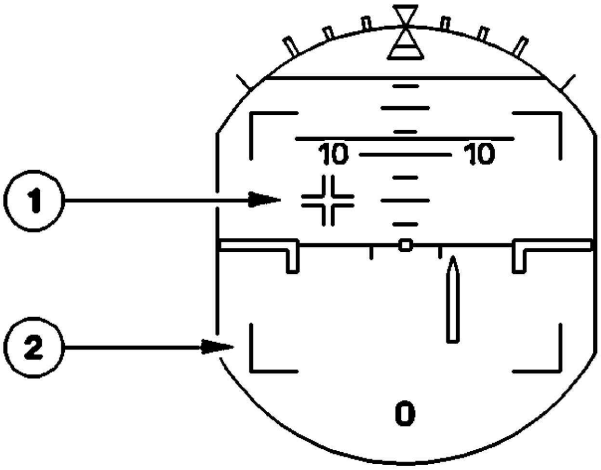
AIRCRAFT ON THE GROUND

Applicable to: ALL

At ground speeds below 70 kt, the sidesticks have full authority over the controls in pitch and roll to permit control checks.
At ground speeds above 70 kt, the authority in pitch is reduced from 30 ° up to 20 ° up.
In this ground mode, movements of the control surfaces in pitch and roll correspond directly to the stick inputs.

With the aircraft in the normal configuration and engines running on the ground :
- when the wheel brakes are released, the aircraft usually rolls with no added thrust.
- nose wheel steering is "fly.by.wire", with no mechanical connection between the nose wheel and the steering tiller. The control forces are light : the flight crew should be careful to move the tiller gently to avoid unnecessarily high-rate turns.

The aircraft can make very tight turns, but the flight crew should resist any tendency to overcontrol. When making tight turns at low ground speed, the crew should hold the selected tiller position, even if the turn radius is shorter than intended, so as to maintain a smooth turn.



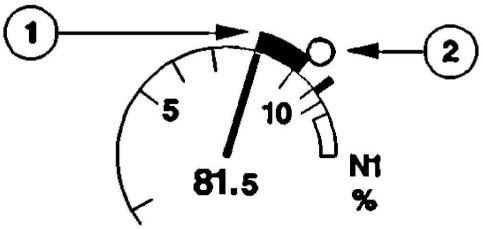
(1) The PFD includes this symbol that is the sum of sidestick positions given to the computers. It permits the PNF to check that the PF is making an appropriate control input during takeoff roll.

(2) Small limit marks indicate the limits of stick travel (±16 ° in pitch, ±20 ° in roll).
They are only displayed with the aircraft on ground. The flight crew must not use this display for control checks, because it does not necessarily indicate the control position in failure cases. The flight crew must use the ECAM flight controls page for making that check.

IN FLIGHT

Applicable to: ALL

TAKEOFF MODE



Thrust management is very easy. The pilot selects a FLX thrust by stopping the thrust levers in the FLX/MCT detent, and by checking that the resulting N1 (or EPR) (1) is compatible with N1 (or EPR) target (2). For maximum takeoff thrust, the pilot moves the thrust levers fully forward and performs the same thrust check (N1 or EPR).

To counter the nose-up effect of setting engine takeoff thrust, the pilot should apply half forward stick, until the airspeed reaches 80 kt. Then, he should release the stick gradually to reach neutral at 100 kt (refer to PRO-NOR-SOP-12 Takeoff for additional information).

Rotation is conventional. It takes about 1/3 to 1/2 back stick. The Pilot Flying (PF) continues the rotation in order to bring the all–engine attitude value towards approximately 15 °. During rotation, the PF must not attempt to reach the FD pitch bar, because it does not provide a pitch rate order, and may lead to overreaction. As soon as the aircraft becomes airborne only, the PF must adjust the pitch attitude using the FD bar, which is then representative of the SRS order. As the attitude changes and stabilizes, the control laws change to those for the flight mode in pitch, allowing the sidestick to return to the neutral position to maintain 1 g at the chosen attitude. Pitch trim can begin to work at 50 ft.

For crosswind takeoffs, routine use of into wind aileron is not recommended. In strong crosswind conditions, some lateral control may be used, but care should be taken to avoid using large deflections, resulting in excessive spoiler deployment which increases the tendency to turn into wind, reduces lift and increases drag. Spoiler deflection starts to become significant with more than one third sidestick deflection. As the aircraft lifts off, any lateral control applied will result in a roll rate demand.

FLIGHT MODE

Normally the sidestick is in the neutral position, with the aircraft stable in pitch and roll at the chosen altitude in straight or turning flight within certain limits. As a result, even in turbulence, the aircraft is flown best with little or no stick input.

Hands off, the system maintains 1 g in pitch, corrected for pitch and roll attitude, and zero roll rate, within certain limits (+30 °, –15 ° in pitch and ± 33 ° roll). Hands off, within these limits the aircraft resists disturbance from the atmosphere and rides well even in heavy turbulence.

The system compensates almost 100 % for changes of trim due to changes in speed and configuration. Changes of trim due to changes in thrust can be too large for the system to compensate, and the aircraft may respond to them in pitch in the conventional sense and then hold the new attitude at which it has stabilized after the trim change.

The pitch trim wheel moves as the control law compensates for these changes.

The control laws also make turning easier. They protect against overbanking, and at the chosen bank attitude (less than 33 ° of bank) the system maintains zero roll rate, stick free.

Steep turns can be made at up to 67 ° of bank. This is the steepest bank at which it is possible to maintain level flight at 2.5 g.

Beyond 33 ° of bank, the pitch trim stops working and a lateral stability term is introduced. This term becomes progressively stronger as bank angle increases, so that it equals a full sidestick demand at 67 ° of bank, hence forming the limiting system.

The lack of pitch trim makes it necessary for the pilot to hold the nose up in a steep turn. If he releases the stick, the nose drops and the aircraft eases its roll angle to less than 33 ° of bank and stabilizes at the pitch and bank angles it achieves at less than 33 ° of bank.

During a normal entry into a turn, the pilot must make an intentional initial change to the pitch attitude in order to maintain level flight. Once he has done this, he can release the stick. The system then maintains a level turn.

In climb, cruise, descent, and approach all these basic rules remain in effect.

LANDING MODE

The system's landing mode gives the aircraft a stabilized flight path and makes a conventional flare and touchdown. It carries out the initial approach as this manual described earlier. At 50 ft, the system memorizes the attitude, usually 3 ° or 4 ° nose up. From 30 ft down, this value washes out over eight seconds to –2 °. The result is that the pilot has to exert a progressive pull to increase pitch gently in the flare. He should pull the thrust levers back at or above 20 ft, and the landing should occur without a long flare. Touchdown quality is better and more repeatable at fairly flat attitudes. An audible "RETARD" callout reminds the pilot if he has not pulled back the thrust levers when the aircraft has reached 20 ft.

Crosswind landings are conventional. The preferred technique is to use the rudder to align the aircraft with the runway heading, during the flare, while using lateral control to maintain the aircraft on the runway centerline (*Refer to PRO-NOR-SOP-21-LANDING-FLARE*). The lateral control

mode does not change until the wheels are on the ground, so there is no discontinuity in the control laws. The aircraft tends to roll gently in the conventional sense as drift decreases, and the pilot may have to use some normal cross control to maintain roll attitude.

Even during an approach in considerable turbulence, the control system resists the disturbances quite well without pilot inputs. In fact, the pilot should try to limit his control inputs to those necessary to correct the flight path trajectory and leave the task of countering air disturbances to the flight control system.

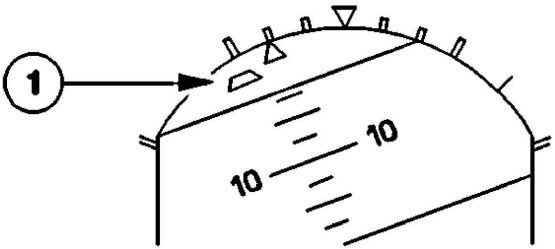
Derotation is conventional. The pilot releases the back pressure he was holding for the flare and the nose wheel comes down nicely.

Pitch trim then resets to zero.

Intentionally left blank

ENGINE FAILURE AT TAKEOFF

Applicable to: ALL



On the ground the aircraft is conventional. The pilot uses rudder to maintain direction. He should rotate to about 12.5 ° of pitch and adjust as required. The sideslip indication (1) changes to the engine-out mode (blue). When it is centered, the aircraft is close to the zero aileron position (best drag condition). It is therefore important to zero the slip indication accurately.

Trim the rudder conventionally.

When time permits, the pilot should check the ECAM's FLT CTL page, and refine the rudder trim to give neutral lateral control, and also trim the rudder toward the spoilers that are up or toward the aileron that is farthest up to bring the lateral controls back to neutral.

ENGINE-OUT LANDING

Applicable to: ALL

The engine-out landing is basically a conventional landing. The pilot should trim to maintain the slip indication centered. It is yellow, as long as N1 is less than 80 %. Between 100 and 50 ft, the pilot can reset rudder trim to make the landing run easier, and to recover full rudder travel in both directions.

BOUNCE AT LANDING

Applicable to: ALL

In case of a light bounce, maintain the current pitch attitude and complete the landing, while maintaining the thrust at idle. In case of a high bounce, initiate a go-around, initially maintaining the pitch attitude. Retract the flaps one step, and then the landing gear, once the aircraft is properly

established on the go-around segment. In all cases, do not attempt to soften the (potential) second touchdown by increasing the pitch attitude.

TRAINING TOUCH-AND-GO

Applicable to: ALL

With the nosewheel on ground, pitch trim automatically resets to zero. The pilot should select CONF 2 and add thrust. He must always move the thrust levers to TOGA to bring up the speed reference system (SRS), and then reduce to a lower thrust (not less than CL), if he chooses. Takeoff may be a little out of trim, which may affect the rotation slightly, but once the aircraft is off the ground, the control law holds the “out of trim”, then retrims at 50 ft.

STALL WARNING

Applicable to: ALL

The applicable procedures have been moved in FCOM PRO-ABN-10 (Operating Techniques) section and in the QRH ABN 80.07.

STALL WARNING AT LIFT-OFF

Refer to PRO-ABN-10 Stall Warning At Lift-Off

STALL RECOVERY PROCEDURE

Refer to PRO-ABN-10 Stall Recovery

ABNORMAL CONTROL LAWS - GENERAL

Applicable to: ALL

ALTERNATE LAW

Pitch alternate and roll direct is the first level of degraded control law, resulting from some double failures.
The autopilot may be available, depending on the cause and type of failure(s).

DIRECT LAW

The sidestick is directly coupled to the controls via the computers, but without any of the stabilization feedbacks. In effect, this law turns the aircraft into a conventional aircraft, but is compensated for configuration and CG. The pilot must use manual pitch trim, as is signaled on the PFD. The autopilot is not available.

MECHANICAL BACKUP

The pilot can use the pitch trim and rudder to control the aircraft for short periods of total loss of fly-by-wire.

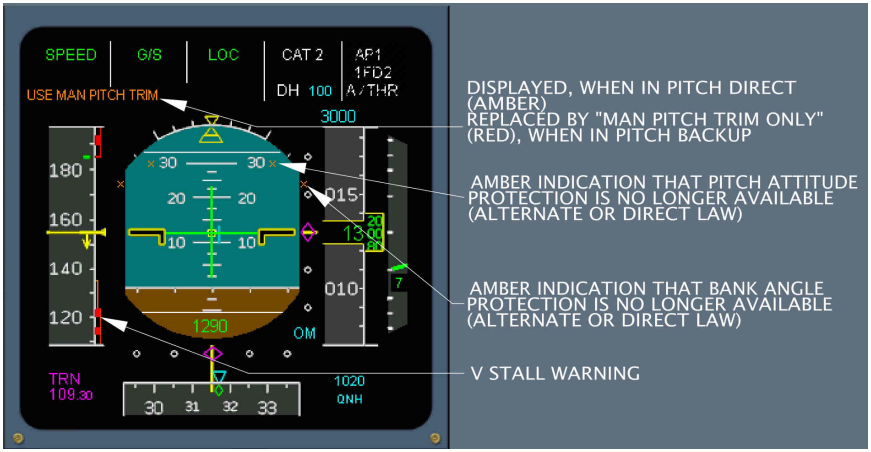
ABNORMAL CONTROL LAWS - IN DETAIL

Applicable to: ALL

ALTERNATE LAW

PITCH

Alternate law in pitch is almost the same (for the pilot) as the normal control laws. However, alternate law does not maintain any of the protections, except for the load factor limitation. As a result, the pilot must fly the aircraft more attentively to avoid inadvertently exceeding the normal limits.
Alternate law reduces VMO to 320 kt to restore a normal aircraft speed margin in case of upset. This is not necessary in the Mach range, because the margin there is, in any case, conventional.



At low speed the change in the speed scale is very noticeable. VLS remains, but Vα PROT and Vα MAX disappear, replaced by a single black and red strip the top of which is stall warning speed. Unlike VLS which is stable, VSW is g sensitive so as to give additional margin in turns. As mentioned above, ALTERNATE reverts to DIRECT law for landing when the flight crew lowers the landing gear.

ROLL

Roll control is direct. The rate of roll is generally higher than with normal law and at first the aircraft appears to be very sensitive.
Bank stability and protections are no longer active and the flight crew should take care to stay within normal limits.

DIRECT LAW

Normally direct law in pitch is transitory, due to undetected failures of, for example, a second IRS. Once the flight crew has isolated the failed system, it can reset the ELACs to acquire alternate law in pitch.
When the system goes into direct law, “USE MAN PITCH TRIM” appears on the PFDs. This message flashes for 5 s, then becomes steady.
The pilot should use small control inputs when the aircraft is in direct law at high speed, because the controls are powerful. Good trimming in pitch is required.
The pilot should avoid using large thrust changes or sudden speedbrake movements, particularly if the center of gravity is aft. If the speedbrakes are out and the aircraft has been retrimmed, the pilot should retract the speedbrakes gently, giving time to retrim so as to avoid a large nose-down trim change.
The flight crew must fly the aircraft carefully at all times. Control is precise, but there are no protections.
The aural stall warning for alternate law also serves direct law, and the technique for recovery is the same.
Any tendency to roll stick free can be corrected by conventional use of rudder. Residual rudder forces can be trimmed out by using rudder trim in the direction of the applied force.
After trimming, the sideslip index will be slightly displaced from center. With some failure conditions the asymmetric rolling tendency may be increased. It will always be possible to trim the aircraft to fly straight, hands off. There may then be an asymmetry in roll response, but the roll rate achieved is always adequate.
Landing in direct law is like landing a conventional aircraft. Trim changes to compensate for configuration changes are small, as is the trim change with speed change. Trim change with a large thrust change is quite large, so the pilot should make smooth thrust changes. The flare height for landing is the same (refer to PRO-NOR-SOP-22 Landing), and the pilot uses conventional techniques. (The controls remain light and powerful).
Pilots have landed this aircraft in direct law in moderate to heavy turbulence with gusting winds without undue difficulty.
Direct law works with or without the yaw damper. The aircraft is always convergent in dutch roll, so if an oscillation begins it will stop itself if not excited. To stop dutch roll the pilot should use lateral inputs, not rudder.

GENERAL

Applicable to: ALL

The aircraft has a comprehensive flight envelope protection system.
This system increases safety if the pilot has to make an extreme maneuver or the aircraft enters a very violent meteorological situation.
In either of these situations, the pilot can make full sidestick inputs in normal laws at any speed. The rudder is not protected in this way, but is not normally used during symmetrical flight.
The pilot will never see any aspect of this envelope protection take effect as long as he flies the aircraft normally.

Note: The normal flight envelope is not different from that of a conventional aircraft, and is defined as VLS to VMO. Pilots should not deliberately fly at a speed that is lower than VLS except for properly authorized training or testing.

PITCH ATTITUDE PROTECTION

Applicable to: ALL

The system limits the aircraft to 67 ° of bank, which corresponds approximately to the bank angle needed for a level 2.5 g turn.
The system limits pitch attitude to +30 ° and –15 °. The +30 ° limit decreases to 25 ° at low speed. If the aircraft attitude approaches these limits, the pitch and roll rates start to decrease 5 ° before the limit so that it will stop at the limit without overshooting.

LOAD FACTOR LIMITATION

Applicable to: ALL

The aircraft is structurally designed to the same limits as any other large aircraft. The 2.5 g limit (2 g with flaps extended) allows the aircraft to make an abrupt maneuver without structural risk if such a maneuver becomes necessary.
When this occurs (after a ground proximity warning, for example), the pilot should quickly apply full control and hold it until the flight path is safe. Response time is a vital factor in avoidance : the system allows maneuvers that the pilot would not normally be able to perform safely at any altitude, low or high.

EXCEEDING VMO/MMO

Applicable to: ALL

During climb, cruise or descent the aircraft may slightly exceed VMO/MMO with the autopilot (AP) engaged. This may occur when adverse conditions are encountered.

Using the following procedure prevents such an exceedance :

1. In case of turbulence, adapt speed or Mach target. If severe turbulence is known, or forecasted, consider the use of turbulence speed.
2. The current speed is close to the VMO (maximum operating speed) :
   - Monitor the speed trend symbol on the PFD :
     - If the speed trend reaches, or slightly exceeds, the VMO limit :
       - Use the FCU immediately to select a lower speed target.
     - If the speed trend significantly exceeds the VMO red band, without high speed protection activation :
       - Select a lower target speed on the FCU and, if the aircraft continues to accelerate, consider disconnecting the AP.
       - Before re-engaging the AP, smoothly establish a shallower pitch attitude.
3. If the aircraft accelerates above VMO with the AP engaged :

   The AP will disengage on reaching the high speed protection. The high speed protection will apply a nose-up order up to 1.75 g, in addition to pilot input during VMO recovery. Therefore :
   - Make a smooth pitch correction, to recover proper speed.

In all events :

- Speedbrakes may be used if the aircraft exceeds VMO/MMO. However, use speedbrakes with caution when close to the ceiling.
- Check the AP engagement status and re-engage it when appropriate. It may have tripped, if VMO/MMO was significantly exceeded. The associated aural warning may have been superseded by the overspeed aural warning.

HIGH SPEED PROTECTION

Applicable to: B-HSI, B-HSM, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The aircraft automatically recovers following a high speed upset. Depending on the flight conditions (high acceleration, low pitch attitude) the high speed protection is activated at/or above VMO/MMO. When it is activated, the pitch trim is frozen, spiral static stability is introduced to 0 ° bank angle (instead of 33 ° in normal law), and the bank angle limit is reduced from 67 ° to 40 °.
As the speed increases above VMO/MMO, the sidestick nose-down authority is progressively reduced, and a permanent nose-up order is applied to aid recovery to normal flight conditions.
The High Speed Protection is deactivated when the aircraft speed decreases below VMO/MMO, where the usual normal control laws are recovered.
The flight crew should never deliberately fly the aircraft beyond VMO/MMO, unless absolutely necessary for operational reasons, such as avoiding another aircraft.
The pilot should, as soon as possible, reduce resistance to the High Speed Protection and allow the aircraft to return to a speed below VMO/MMO, by smoothly relaxing the forward stick force to attain a comfortable nose-up pitch rate. It is not usually necessary to apply a pull force to recover. If a quicker

recovery is required for operational reasons, the pilot should pull back smoothly and progressively, monitoring the g indication on the ECAM.

HIGH SPEED PROTECTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSJ, B-HSK, B-HSL, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The aircraft automatically recovers following a high speed upset. Depending on the flight conditions (high acceleration, low pitch attitude), the High Speed Protection is activated at, or above, VMO/MMO.
When it is activated, spiral static stability is introduced to 0 ° bank angle (instead of 33 ° in normal law), and the bank angle limit is reduced from 67 ° to 40 °.
As the speed increases above VMO/MMO, the sidestick nose-down authority is progressively reduced, and a permanent nose-up order is applied to aid recovery to normal flight conditions.
The High Speed Protection is deactivated when the aircraft speed decreases below VMO/MMO, where the usual normal control laws are recovered.
The flight crew should never deliberately fly the aircraft beyond VMO/MMO, unless absolutely necessary for operational reasons, such as avoiding another aircraft.
The pilot should, as soon as possible, reduce resistance to the High Speed Protection and allow the aircraft to return to a speed below VMO/MMO, by smoothly relaxing the forward stick force to attain a comfortable nose-up pitch rate. It is not usually necessary to apply a pull force to recover. If a quicker recovery is required for operational reasons, the pilot should pull back smoothly and progressively, monitoring the g indication on the ECAM.

HIGH ANGLE OF ATTACK PROTECTION

Applicable to: ALL

The aircraft resists attempts by either a pilot or the atmosphere to stall it. If a pilot attempts a stall, he feels the aircraft trying to pitch down as speed approaches the amber and black strip. The pilot can resist this tendency until speed reaches the red band (alpha maximum), and then further nose-up control is not available. Between these two points, αfloor automatically sets go around thrust. The pilot can hold full back stick, if it is needed (see windshear), and the aircraft stabilizes at an angle of attack close to but short of the 1 g stall.
WHEN FLYING AT αmax, THE PILOT CAN MAKE GENTLE TURNS, IF NECESSARY.
As the aircraft enters protection at the amber and black strip. (αprot), the system inhibits further nose-up trim beyond the point already reached. Nose-down trim remains available if the pilot pushes the stick forward.
The pilot should not deliberately fly the aircraft in αprot except for brief periods when maximum maneuvering is required. If the pilot enters αprot inadvertently, he should get out of it as quickly as possible by easing forward on the sidestick to reduce the angle of attack while simultaneously adding power (if αfloor has not already been activated or has been cancelled). The system will regain the

normal load factor law if the stick is pushed forward of neutral, but it will re-enter αprot if the stick is released with the angle of attack still greater than the value set for αprot. Thus to exit αprot properly, the pilot should reduce angle attack to a value less than the value set for αprot.
The PFD shows this clearly, because the indicated speed is above the black and amber strip.
The pilot should now increase speed above VLS (clear of the amber strip) as soon as other considerations (ground clearance, for example) allow him to do so.
αfloor will usually be triggered just after αprot is entered, and go around thrust will automatically be applied. Thus, if the sidestick is held aft, either inadvertently or deliberately, the aircraft will start to climb at a relatively constant low airspeed. To recover to a normal flight condition, αprot should be exited by easing forward on the sidestick, as described above, and the αfloor should be cancelled by using the disconnect pushbutton on either thrust lever as soon as a safe speed is regained.
The aircraft can also enter αprot at a high level, where it protects the aircraft from the buffet boundary. As at low speed or low level, if the sidestick is merely released to neutral, the aircraft maintains the alpha for αprot. (However, this value of alpha is not the same as the value used at low speed : Alpha for αprot is reduced as a function of Mach, so that a typical cruise value is about 3.5 ° for the A318 and A321 aircraft, or 4.5 ° for the A319 and A320 aircraft). Therefore, the aircraft may climb, with the sidestick free, when leaving a turn after entering αprot. If the pilot has flown into αprot, he should leave it as soon as other considerations allow, by easing forward on the sidestick to reduce alpha below the value of αprot, while simultaneously increasing thrust or speed as appropriate.

WINDSHEAR

Applicable to: ALL

Most of the recommended techniques for flight in windshear also apply to the A320 aircraft family. But for these aircraft, the techniques are somewhat simpler.

The aircraft can only survive windshear, if it has enough energy to carry it through the loss-of-performance field. The aircraft can sustain this energy level in the following three ways :
- Carry extra speed. The aircraft does this automatically in some cases.
- Add maximum thrust. The aircraft does this automatically.
- Trade height energy for speed. Any aircraft can do this.

Proper pilot technique helps in this survival process. The pilot must follow orders from the Speed Reference System (SRS) or, if the FD is not available or is switched OFF for a visual approach, maintain 17.5 ° of pitch, even if he has to use full backstick in order to do so. At this stage, maintain full backstick until the shear is passed. The aircraft will automatically hold close to the maximum Angle-Of-Attack. The speed should stay near to the beginning of the red strip. However, in turbulence, the speed can be temporarily below the red strip without significant effect. As speed

begins to recover, the pilot can reduce backstick, while still following SRS orders until well clear of the shear.

ABNORMAL CONFIGURATIONS

Applicable to: ALL

In some flight control failure cases, such as loss of control of both elevators, or loss of flaps or slats, the landing configuration is Configuration 3.
With the horizontal stabilizer jammed, control is much easier than it is on a conventional aircraft, because the integrator holds the elevator required to maintain the 1 g flight path.
The control laws remain normal to touchdown.

Intentionally left blank

AIRCRAFT TRIMMING

Applicable to: ALL

When the aircraft is :

- In normal cruise range (around M .77),
- In straight flight,
- With the autopilot engaged,
- With symmetrical engine thrust, and
- With fuel in the wing tanks distributed symmetrically,

the rudder trim should stay between 1 ° right and 2.3 ° left.

Note: *This indication corresponds to a true rudder deflection within ± 1.5 °, taking into account the permanent offset of rudder trim indication, when the aircraft is in cruise conditions. (average 0.5 ° right, 0.8 ° left).*
An indicated, rudder trim above 1 ° right or 2.3 ° left is acceptable, if maintenance personnel establishes that the corresponding real rudder position is within 1.5 ° left, and 1.5 ° right.

Intentionally left blank

FQI IN DEGRADED MODE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

If, on upper ECAM display the FOB indication is displayed with two dashes across the two least significant digits, the FQI is in degraded mode.
In this case, the ECAM FUEL page must be called on ECAM lower display to determine which tank is affected.

The loss of accuracy resulting from the loss of FQI normal mode is as follows :

wing outer cell affected	:	+20 kg (+44 lb), –200 kg (–440 lb).
wing inner cell affected	:	±110 kg (240 lb).
center tank affected	:	±130 kg (290 lb).
all tanks affected	:	+ 390 kg (+ 860 lb), –750 kg (–1660 lb).

FQI IN DEGRADED MODE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

If, on upper ECAM display the FOB indication is displayed with two dashes across the two least significant digits, the FQI is in degraded mode.
In this case, the ECAM FUEL page must be called on ECAM lower display to determine which tank is affected.

The loss of accuracy resulting from the loss of FQI normal mode is as follows :

wing tank affected	:	+ 130 kg (+ 290 lb), –310 kg (–690 lb).
center tank affected	:	±130 kg (290 lb).
all tanks affected	:	+ 390 kg (+ 860 lb), –750 kg (–1660 lb).

Intentionally left blank

ICING CONDITIONS

Applicable to: ALL

Icing conditions may be expected when the OAT (on ground and for takeoff), or when the TAT (in flight) is at or below 10 °C, and there is visible moisture in the air (such as clouds, fog with low visibility of one mile or less, rain, snow, sleet, ice crystals) or standing water, slush, ice or snow is present on the taxiways or runways.

WARNING	Pilots must turn on the engine anti-ice system, when temperature and visible moisture meet these criteria, and should not wait until they see ice building up.

OPERATIONS IN ICING CONDITIONS

Applicable to: ALL

FLIGHT IN ICING CONDITIONS

- **Engine anti-ice**

  ENGINE ANTI ICE must be ON during all ground and flight operations, when icing conditions exist, or are anticipated, except during climb and cruise when the SAT is below -40 °C.

  ENGINE ANTI ICE must be ON before and during a descent in icing conditions, even if the SAT is below -40 °C.

- **Wing anti-ice**

  WING ANTI ICE may either be used to prevent ice formation, or to remove ice accumulation from the wing leading edges.

  WING ANTI ICE should be selected ON, whenever there is an indication that airframe icing exists. This can be evidenced by ice accumulation on the visual ice indicator (located between the two cockpit windshields), or on the windshield wipers.

CAUTION	1. Extended flight, in icing conditions with the slats extended, should be avoided. 2. If there is evidence of significant ice accretion and to take into account ice formation on non heated structure, the minimum speed should be : - In configuration full, VLS +5 kt, and the landing distance must be multiplied by 1.1. - In configuration lower than FULL, VLS +10 kt, and the landing distance in CONF 3 must be multiplied by 1.15. 3. If there is evidence of ice accretion on de-iced parts (WING ANTI ICE inoperative) of the airframe, the minimum speeds should be : - In clean configuration, VLS + 15 kt. - In CONF 1, 2, 3, FULL, VLS + 10 kt, For landing distance determination, *Refer to FCOM-QRH ABN 80 LDG CONF/APPR SPD/LDG DIST TABLES* following failures tables.

SEVERE ICE ACCRETION

Applicable to: ALL

Icing conditions are severe when there is approximately 5 mm of ice accretion on the airframe.

RAIN REPELLENT (IF INSTALLED)

Applicable to: ALL

If the rain repellent is operative, the flight crew should only use the rain repellent in moderate to heavy rain.

GROUND OPERATIONS IN HEAVY RAIN

Applicable to: ALL

When the aircraft is parked on the ground during heavy rain, it can take rainwater into the avionics ventilation system via the open skin air inlet valve.
To prevent this, the following procedure must be applied :

- **After landing :**
  EXTRACT.....OVRD
  This closes the avionics ventilation system, preventing rainwater from entering.

PACKS 1 and 2..... CHECK ON

This adds air from the air conditioning system to ventilation air. If bleed air is not available, the arrangement can function for a limited time, as follows :

- *OAT ≤39 °C : no limit*
- *39 °C ≤OAT ≤45 °C : 3 h*
- *OAT ≥45 °C : 30 min*

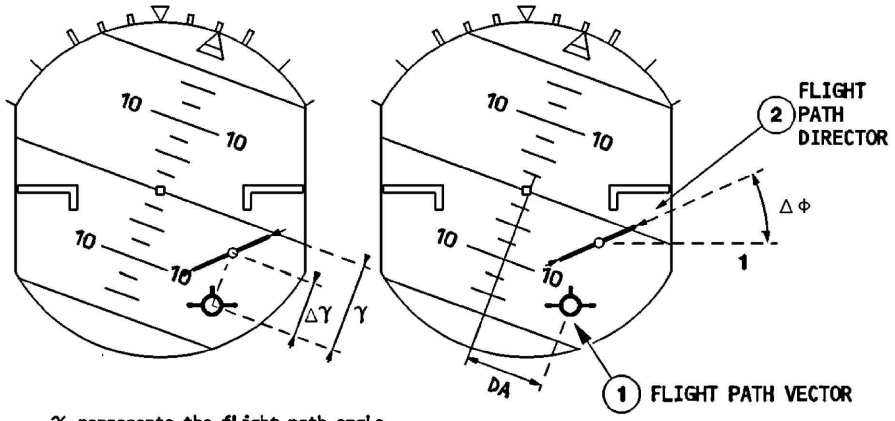
● **After takeoff :**

EXTRACT..... AUTO

Intentionally left blank

USE OF FLIGHT PATH VECTOR

Applicable to: ALL



Υ represents the flight path angle
DA represents the drift angle
ΔΥ represents the difference between the ordered flight path angle and the actual one
Δ Φ represents the difference between the ordered roll angle and the actual one

The flight path vector (FPV) indicates performance and does not direct or command. Because there is always a slight lag between an attitude change and the change in flight path that results from it, when the pilot uses the FPV he should make an attitude change first, then use the FPV to check the resulting flight path.

Vertically the FPV indicates the aircraft's flight path angle.

The FPV is particularly useful when the aircraft is doing visual circuits. For example, when the aircraft is flying downwind the pilot simply adjusts the aircraft attitude to put the FPV symbol on the horizon. This establishes the aircraft in level flight. On the final approach, the pilot puts the FPV three degrees below the horizon to establish the aircraft at a normal angle of descent. If this results in the aircraft going below the chosen approach path (undershooting the touchdown point), the pilot can reduce the angle of descent by raising the FPV. As soon as the aircraft regains the correct descent path, he should bring the FPV back to -3 °.

Laterally, the FPV indicates the aircraft's track and its drift angle. It has the same displacement as the drift diamond on the heading scale and thus appears directly above it. It shows on the PFD the drift the aircraft is experiencing.

The pilot must take care when making a go-around with the FPV selected. There is inevitably some lag between the pilot's raising the nose to commence the go-around and the aircraft's responding by changing its trajectory. For the same reason the pilot does not use the FPV on takeoff: the primary parameter for rotation, either on takeoff or on go-around, is attitude.

The TRK-FPA Flight Director is particularly useful for guiding the aircraft during non-precision approaches, although it can also be used at other times. When using this mode of the FD, the pilot places the FPV symbol in the center of the flight path director (FPD) symbol. This is similar to using the FD in HDG-V/S, when the pilot puts the center of the fixed aircraft symbol at the center of the crossed bars of the FD. If the FCU is set on the correct track and flight path angle, and if the FPV and the FPD are aligned, they will guide the aircraft along a trajectory that is stabilized with respect to the ground, whereas when the pilot is using HDG-V/S the trajectory is stabilized with respect to the air. However, if the aircraft is disturbed from this ideal trajectory, merely following the FPD will result in its following a trajectory that is parallel to the intended trajectory. Thus, when the aircraft is disturbed from the original trajectory, the pilot must adjust either its track or its flight path angle or both in order to obtain guidance back to the original trajectory. Likewise, when the pilot uses the FPA to create a synthetic glide path, it will be positioned correctly only if it commences at the right point in space.

BSCU RESET - ON GROUND

Applicable to: B-HSD, B-HSG, B-HSI, B-HSK, B-HTH, B-HTI
Impacted by TDU: 00014191 BSCU Reset - On Ground

Before any BSCU reset, the flight crew must stop the aircraft, apply the parking brake and confirm that the towing bar is not connected. The flight crew must reset the BSCU by setting the A/SKID & N/W STRG sw to OFF then ON.

- Only if the ECAM triggers either the WHEEL N.W STEER FAULT or the WHEEL N/W STRG FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is successful, the flight crew are still required to go back to the gate for troubleshooting. The flight crew must taxi with care, at a taxi speed of 10 kt.
- Only if the ECAM triggers either the BRAKES SYS 1(2) FAULT or the BRAKES BSCU CH 1(2) FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is not successful, the flight crew may attempt a further reset by using the BSCU circuit breakers. After a successful reset, the flight crew can continue the flight.
- On ground, after any BSCU reset, the flight crew must perform all of the following:
  - Check the braking efficiency of the normal braking system, as soon as the aircraft starts moving again (the aircraft must slow down when pressing the brake pedals).
  - Record the BSCU reset in the logbook to ensure that troubleshooting is systematically done, in order to investigate the failure.

BSCU RESET - ON GROUND

Applicable to: B-HSE, B-HSJ, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTD, B-HTE, B-HTF, B-HTG

Before any BSCU reset, the flight crew must stop the aircraft, apply the parking brake and confirm that the towing bar is not connected. The flight crew must reset the BSCU by setting the A/SKID & N/W STRG sw to OFF then ON.

- Only if the ECAM triggers either the WHEEL N.W STEER FAULT or the WHEEL N/W STRG FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is successful, the flight crew are still required to go back to the gate for troubleshooting. The flight crew must taxi with care, at a taxi speed of 10 kt.
- Only if the ECAM triggers either the BRAKES SYS 1(2) FAULT or the BRAKES BSCU CH 1(2) FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is not successful, the flight crew may attempt a further reset by using the BSCU circuit breakers. After a successful reset, the flight crew can continue the flight.
- On ground, after any BSCU reset, the flight crew must perform all of the following:
  - Check the braking efficiency of the normal braking system, as soon as the aircraft starts moving again (the aircraft must slow down when pressing the brake pedals).
  - Record the BSCU reset in the logbook to ensure that troubleshooting is systematically done, in order to investigate the failure.

BSCU RESET - ON GROUND

Applicable to: B-HSD, B-HSG, B-HSI, B-HSK, B-HTH, B-HTI
Impacted DU: 00002184 BSCU Reset - On Ground

Before any BSCU reset, the flight crew must stop the aircraft, apply the parking brake and confirm that the towing bar is not connected. The flight crew must reset the BSCU by setting the A/SKID & N/W STRG sw to OFF then ON.

- Only if the ECAM triggers either the WHEEL N.W STEER FAULT or the WHEEL N/W STRG FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is successful, the flight crew are still required to go back to the gate for troubleshooting. The flight crew must taxi with care, at a taxi speed of 10 kt.

  Note: If during taxi, when the aircraft is moving, the ECAM displays the NW STRG DISC amber memo along with the WHEEL N.W STEER FAULT or WHEEL N/W STRG FAULT ECAM alert, the flight crew may attempt to perform only one BSCU reset. The flight crew can continue the flight if the above-mentioned ECAM alert and memo are no longer displayed after this BSCU reset.

- Only if the ECAM triggers either the BRAKES SYS 1(2) FAULT or the BRAKES BSCU CH 1(2) FAULT alert, can the flight crew attempt a BSCU reset. If the BSCU reset is not successful, the flight crew may attempt a further reset by using the BSCU circuit breakers. After a successful reset, the flight crew can continue the flight.
- On ground, after any BSCU reset, the flight crew must perform all of the following:
  - Check the braking efficiency of the normal braking system, as soon as the aircraft starts moving again (the aircraft must slow down when pressing the brake pedals).
  - Record the BSCU reset in the logbook to ensure that troubleshooting is systematically done, in order to investigate the failure.

BSCU RESET - IN FLIGHT

Applicable to: ALL

Only if the ECAM triggers either the BRAKES SYS 1(2) FAULT or the BRAKES BSCU CH 1(2) FAULT alert, can the flight crew attempt a BSCU reset. The flight crew must reset the BSCU, landing gear retracted, by setting the A/SKID & N/W STRG sw to OFF then ON.

Note: Extending the landing gear initiates an automatic test of the main braking components, in order to detect any failures. If the flight crew resets the BSCU with the main landing gear already extended, the failures and associated ECAM indications that are already detected are erased, even if the BSCU reset does not necessarily correct the failure. Therefore, in order to detect any remaining failures, the flight crew must reset the BSCU before landing gear extension.

If required, the flight crew must rearm the autobrake. In flight, after any BSCU reset, the flight crew must record the BSCU reset in the logbook to ensure that troubleshooting is systematically done, in order to investigate the failure before the next flight.

BRAKING IN ALTERNATE MODE

Applicable to: ALL

Apply brakes with care, because initial pedal force or displacement produces more braking action in alternate mode than in normal mode. If antiskid is lost, modulate brake pressure at, or below, 1 000 PSI.

THRUST APPLICATION ON BRAKES

Applicable to: ALL

The braking system is not designed to hold the aircraft in a stationary position when a high thrust level is applied on at least one engine.

The thrust level from which the aircraft starts to move (with parking brake ON, or with manual braking applied) depends on several factors such as:

- Ground surface conditions
- Environment
- The aircraft weight
- Etc...

During ground procedures that require a thrust increase with braking, the flight crew must ensure that the aircraft remains stationary, and one flight crew must keep his hands on the thrust levers to be ready to immediately retard the thrust levers to IDLE if the aircraft starts to move.

BRAKE TEMPERATURE LIMITATIONS REQUIRING MAINTENANCE ACTIONS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Maintenance action is required in the following cases:

- The temperature difference between the 2 brakes on the same gear is greater than 150 C, and the temperature of either one of the brakes is higher than, or equal to 600 C, or
- The temperature difference between the 2 brakes on the same gear is greater than 150 C, and the temperature of one brake is lower than, or equal to 60 C, or
- The difference between the average temperature of the left gear brakes and the average temperature of the right gear brakes is 200 C or more, or
- A fuse plug has melted, or
- One brake's temperature exceeds 900 C.

BRAKE TEMPERATURE LIMITATIONS REQUIRING MAINTENANCE ACTIONS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Maintenance action is required in the following cases:

- The temperature difference between the 2 brakes on the same gear is greater than 150 C, and the temperature of either one of the brakes is higher than, or equal to, 600 C or
- The temperature difference between the 2 brakes on the same gear is greater than 150 C, and the temperature of one brake is lower than, or equal to 60 C,or
- The difference between the average temperature of the left gear brakes and the average temperature right gear brakes is 200 C or more,or
- A fuse plug has melted, or
- One brake's temperature exceeds 800 C.

OPERATION WITH NOSEWHEEL STEERING OFFSET

Applicable to: ALL

GENERAL

During taxi, the crew may notice an aircraft veering tendency. This can be due to some external conditions (crosswind, slope....), or it can be due to the nosewheel steering system itself. The latter case is identifiable due to flight crews' consecutive reports of permanent aircraft veering tendency. Such reports enable maintenance to determine when corrective action or troubleshooting is required.

A veering aircraft may still be operated before corrective action is taken, provided nosewheel steering deviation is within the values specified in the following table.

NWS OFFSET OPERATIONAL LIMITATION

NWS Offset	Offset ≤ 0.5 °	0.5 °<Offset ≤ 1.5 °	Offset >1.5 °
Rudder trim to taxi straight	Trim ≤ 3 °	3 °<Trim ≤ 8.8 °	Trim >8.8 °
Procedures	No operational limitation	Apply the following procedure : Autoland: - MAX X WIND ...10 kt	Immediate maintenance action is due

CAUTION	The tolerance required by maintenance guidelines (± 0.5 ° NWS offset, corresponding to the ± 3 ° rudder trim necessary to taxi straight) remains valid. Operating the aircraft outside the maintenance tolerance is possible by using the applicable procedure. However, in such cases, the flight crew must accurately and systematically make logbook entries (indicating the rudder trim input value to taxi straight) to ensure that maintenance can take corrective action within the applicable timeframe. When using rudder trim to taxi straight for NWS offset identification, takeoff must only be performed after a rudder trim reset.

TIRE PRESSURE

Applicable to: ALL

Tyre pressures are checked according to a regulated maintenance schedule.

BRAKE AND TIRE WEAR LIMITS

Applicable to: ALL

Brake and tire checking are primarily maintenance functions. However, if a brake wear indicator is observed to be flush or a tire has no evidence of tread, has deep cuts or flat spots, then the dispatching engineer or IOC MC if the station is unmanned, should be consulted for confirmation the component is serviceable for the intended flight.

BRAKE COOLING

Applicable to: ALL

When brake temperatures are above 400 C and the turn-around time is short, use brake cooling with the parking brake off. The parking brake should only be released after confirmation the wheel chocks are in place.

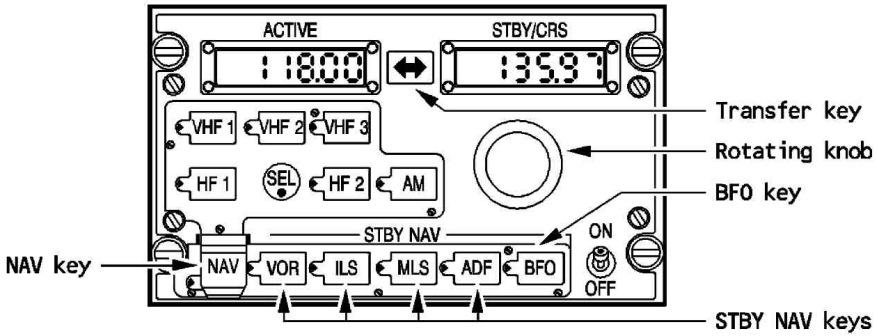
- Temperature >450 C may result in smoke from the brake due to fluid contamination in the vicinity of or on the brake unit.
- Temperature >500 C, confirm chocks in place, release park brake and apply brake cooling to prevent acidification of hydraulic fluid in brake pistons due to heat transference.
- Temperature rising above 600 C may indicate a brake fire. Immediate clarification must be sought from ATC, other aircraft or fire services.

PROCEDURES FOR TUNING STANDBY NAVIGATION RADIOS

Applicable to: ALL

GENERAL

CAUTION	Pilots should use these procedures only when both FMGCs or both MCDUs are inoperative. In this case they must press both RMP NAV keys (lighting the green lights).



FOR BOTH RMPS

ON/OFF Switch.....CHECK ON
NAV key (guarded).....PRESS

Green light comes on.
A lighted STBY NAV key shows which system had been selected earlier in the radio-nav standby mode, and the windows show which frequencies had been used.

ON THE RMP ASSOCIATED WITH THE RECEIVER TO BE TUNED

Select a STBY NAV system :

● **ADF tuning :**

ADF key.....PRESS

The green light comes on.
The windows show the previously selected frequencies.

Rotating knob..... TURN

Watch the STBY/CRS window to set a frequency.
The outer knob changes units, inner knob decimals.

Transfer key..... PRESS

This interchanges the ACTIVE and STBY frequencies. The ADF receiver is now tuned to the new ACTIVE frequency.

BFO key (if necessary)..... PRESS

Green light comes on.

● **VOR (or ILS) tuning :**

VOR (or ILS) key..... PRESS

Green light comes on.
Both windows display previously selected frequencies.

Rotating knob..... TURN

Set the frequency in the STBY/CRS window.

Transfer key..... PRESS

The ACTIVE window displays the selected frequency.
The STBY/CRS window displays the frequency that had been displayed in the ACTIVE window.

Rotating knob..... TURN

Set the course on the STBY/CRS window.
The receiver is now tuned to the frequency of the new station, and the course is selected.
To select another station, press the transfer (making both windows display the previously selected frequency) before retuning the VOR (or ILS).

Note: When the radio-nav standby mode is active (NAV ON) and VHF or HF tuning is required, select the VHF key or the HF key on the RMP (normal radio communications use). The NAV key, which has no effect on the selection of a radio communication frequency, must remain in the ON position in order to prevent radio navigation aid tuning from changing NAV receiver frequencies.

AUTOMATIC IDENTIFICATION OF ADF/VOR/ILS

Applicable to: ALL

Although the navigation display automatically identifies the tuned ADF, VOR, or ILS station (auto ident decoded), the flight crew must, in the following cases, confirm the correct tuning of the desired station via the audio system :

- A station has either been autotuned or tuned manually by a crew member's entering the associated ident on the MCDU RAD NAV page, and the decoded ident appearing on the ND is the wrong one.
- A crew member has tuned the station manually on an RMP or by entering the frequency on the MCDU RAD NAV page.

WEATHER RADAR

Applicable to: ALL

Refer to FCTM/SI-70 USE OF RADAR

FLIGHT INSTRUMENT TOLERANCES

Applicable to: ALL

GENERAL

The values below apply to aircraft in symmetrical flight (no sideslip), in the clean configuration, and in straight and level flight.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

ALTITUDE TOLERANCES

- PFD 1 or 2 at ground check : plus or minus 25 ft (8 m)
- standby altimeter at ground check : plus or minus 300 ft (91 m)

Note: On ground, as the standby altimeter's vibrator is off, the standby altimeter's tolerance value is high. In flight, the vibrator is on and the value is lower.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

ALTITUDE TOLERANCES

PFD 1 or 2 at ground check : plus or minus 25 ft (8 m)

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

MAXIMUM DIFFERENCES BETWEEN ALTITUDE INDICATIONS

FL/SPEED	ALTITUDE (ft) COMPARISON BETWEEN		
	ADR 1 and ADR 2 (on PFD)	ADR 3 and ADR 1, or ADR 3 and ADR 2 (on PFD)	STBY ALTI and any ADR 1, or 2, or 3
GND CHECK	20 (6 m)	20 (6 m)	(1)
FL 50/250 kt	50 (15 m)	80 (24 m)	130 (40 m)
FL 100/250 kt	55 (17 m)	80 (24 m)	185 (56 m)
FL 200/300 kt	90 (27 m)	145 (44 m)	295 (90 m)
FL 300/.78	130 (40 m)	355 (108 m)	390 (119 m)
FL 390/.78	130 (40 m)	365 (111 m)	445 (136 m)

(1) On ground, the check is meaningless because the standby altimeter's vibrator is off.

Applicable to: B-HSK, B-HTG, B-HTH, B-HTI

MAXIMUM DIFFERENCES BETWEEN ALTITUDE INDICATIONS

FL/SPEED	ALTITUDE (ft) COMPARISON BETWEEN		
	ADR 1 and ADR 2 (on PFD)	ADR 3 and ADR 1, or ADR 3 and ADR 2 (on PFD)	STBY ALTI and any ADR 1, or 2, or 3
GND CHECK	20 (6 m)	20 (6 m)	(1)
FL 50/250 kt	50 (15 m)	65 (20 m)	130 (40 m)
FL 100/250 kt	55 (17 m)	80 (24 m)	185 (56 m)
FL 200/300 kt	90 (27 m)	135 (41 m)	295 (90 m)
FL 300/.78	130 (40 m)	195 (59 m)	390 (119 m)
FL 390/.78	130 (40 m)	195 (59 m)	445 (136 m)

(1) On ground, the check is meaningless because the standby altimeter's vibrator is off.

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

MAXIMUM DIFFERENCES BETWEEN ALTITUDE INDICATIONS

FL/SPEED	ALTITUDE (ft) COMPARISON BETWEEN		
	ADR 1 and ADR 2 (on PFD)	ADR 3 and ADR 1, or ADR 3 and ADR 2 (on PFD)	ISIS and any ADR 1, or 2, or 3
GND CHECK	20 (6 m)	20 (6 m)	100 (30 m)
FL 50/250 kt	50 (15 m)	65 (20 m)	130 (40 m)
FL 100/250 kt	55 (17 m)	80 (24 m)	185 (56 m)
FL 200/300 kt	90 (27 m)	135 (41 m)	295 (90 m)
FL 300/.78	130 (40 m)	195 (59 m)	390 (119 m)
FL 390/.78	130 (40 m)	195 (59 m)	445 (136 m)

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HTD, B-HTE, B-HTF

AIRSPEED/MACH TOLERANCES

Maximum differences between Speed/Mach indications :

FL/SPEED	SPEED (kt) MACH COMPARISON BETWEEN					
	ADR 1 and ADR 2 (on PFD)		ADR 3 and ADR 1, or ADR 3 and ADR 2		STBY ASI and any ADR 1, or 2, or 3

Applicable to: ALL

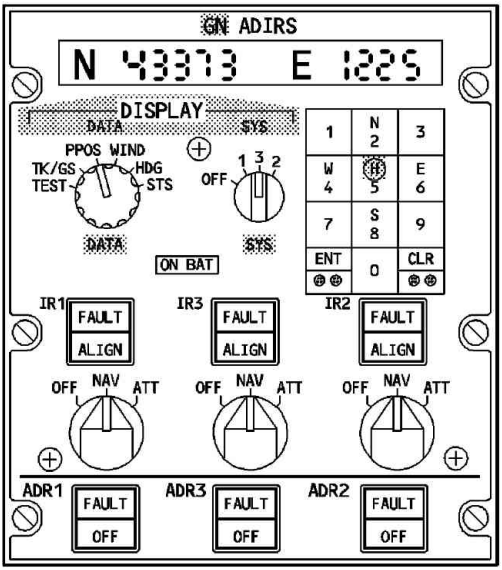
HEADING TOLERANCES

Maximum differences between magnetic heading indications on the NDs : 4 °.

ADIRS OPERATION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

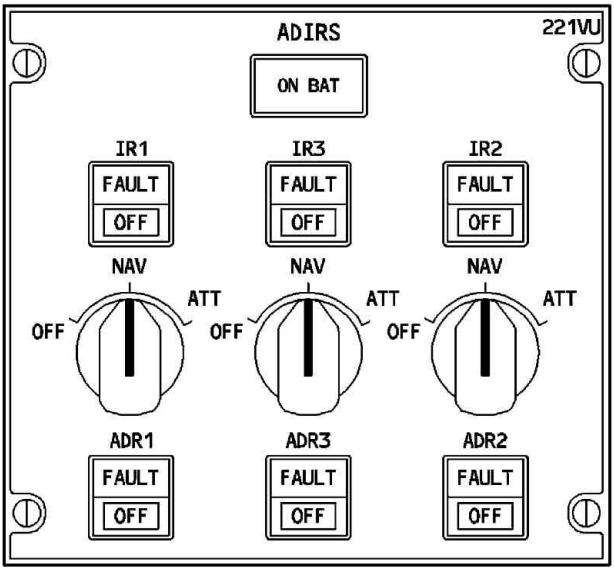
GENERAL



The ADIRS must be aligned : This allows them to operate in NAV mode, to continuously provide the aircraft's position. To complete the alignment, the ADIRS must be initialized to a navigation starting point, from which the ADIRS determine subsequent aircraft positions during flight.
The pilot may check the ADIRS status, and the ADIRS drift, at any moment on the MCDU POSITION MONITOR page.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

GENERAL



The ADIRS must be aligned : This allows them to operate in NAV mode, to continuously provide the aircraft's position. To complete the alignment, the ADIRS must be initialized to a navigation starting point, from which the ADIRS determine subsequent aircraft positions during flight.
The pilot may check the ADIRS status, and the ADIRS drift, at any moment on the MCDU POSITION MONITOR page.

Applicable to: ALL

COMPLETE OR FAST ALIGNMENT

For alignment, the aircraft must be stationary on ground. Any aircraft motion will automatically restart the alignment. Avoid alignment during an engine start, or while the engines are running.
The pilot may choose to perform a complete alignment (this takes about 10 min) or a fast alignment (this takes about 30 s). In both cases, the ADIRS must be initialized to a navigation starting point.
During a complete alignment, the ADIRS uses gravity to determine the aircraft attitude. It then determines true heading, and estimates the present latitude.
During a fast alignment, the ADIRS resets the ground speed to 0. Therefore, the ADIRS will start the position computation with an accurate initial speed. The ADIRS does not estimate the latitude.

The procedure for ADIRS complete or fast alignment is the following :

All 3 ADIRS Control Panel mode selectors.....OFF

The ALIGN light remains OFF.

All 3 ADIRS Control Panel mode selectors..... NAV

If the mode selectors are set back to NAV within 5 s, the ADIRS perform a fast alignment.
Otherwise, the ON BAT light comes ON for 5 s, and the ADIRS then start a complete alignment.

The ALIGN light comes ON, and remains steady until the alignment is complete.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

POSITION INITIALIZATION

The alignment phase is completed, when the ADIRS is initialized to an appropriate position.
Perform this initialization as soon as possible, to prevent delays if an alignment error occurs.

MCDU coordinates..... CHECK/MODIFY

When the pilot enters or modifies the origin airport (FROM) or the CO RTE, the MCDU INIT coordinates are reset to the airport reference point (extracted from the FMS database). The pilot may also manually modify these coordinates.
If the MCDU coordinates change, when the ADIRS are already in NAV mode, the RESET IRS TO NAV message is triggered on the MCDU : Crosscheck the MCDU INIT coordinates against the IRS position on the MCDU POSITION MONITOR page.
When the GPS is available, or for flights in good radio navigation coverage airspace, initialize the ADIRS to the airport reference point extracted from the FMS database. This reduces the risk of entering incorrect values.
If the GPS is not available, and long segments in poor radio navaid coverage airspace are expected, initialize the ADIRS to the gate coordinates. This increases the accuracy of the ADIRS position computation.
If the airport reference point is not stored in the FMS database, and the gate coordinates are not available, use the airport reference point coordinates from the airport chart.

ALIGN IRS prompt.....PRESS

The MCDU INIT page coordinates are sent to the ADIRS, and their navigation starting point is set.

Applicable to: B-HSO, B-HSP

POSITION INITIALIZATION

The alignment phase is completed, when the ADIRS is initialized to an appropriate position.
If the GPS is available, initialization is automatic, using the GPS position. Pilot intervention is not necessary.

However, automatic initialization may be manually overriden by pilot entry, at any moment during the alignment phase. In this case, perform the following procedure as soon as possible, to prevent delays if an alignment error occurs :

MCDU coordinates..... CHECK/MODIFY

When the pilot enters or modifies the origin airport (FROM) or the CO RTE, the MCDU INIT coordinates are reset to the airport reference point (extracted from the FMS database). The pilot may also manually modify these coordinates.
If the MCDU coordinates change, when the ADIRS are already in NAV mode, the RESET IRS TO NAV message is triggered on the MCDU : Crosscheck the MCDU INIT coordinates against the IRS position on the MCDU POSITION MONITOR page.
When the GPS is available, or for flights in good radio navigation coverage airspace, initialize the ADIRS to the airport reference point extracted from the FMS database. This reduces the risk of entering incorrect values.
If the GPS is not available, and long segments in poor radio navaid coverage airspace are expected, initialize the ADIRS to the gate coordinates. This increases the accuracy of the ADIRS position computation.
If the airport reference point is not stored in the FMS database, and the gate coordinates are not available, use the airport reference point coordinates from the airport chart.

ALIGN IRS prompt.....PRESS

The MCDU INIT page coordinates are sent to the ADIRS, and their navigation starting point is set.

Applicable to: B-HSQ, B-HSR

POSITION INITIALIZATION

The alignment phase is completed, when the ADIRS is initialized to an appropriate position.
If the GPS is available, initialization is automatic, using the GPS position. Pilot intervention is not necessary.
However, automatic initialization may be manually overriden by pilot entry, at any moment during the alignment phase. In this case, perform the following procedure as soon as possible, to prevent delays if an alignment error occurs :

MCDU coordinates..... CHECK/MODIFY

When the pilot enters or modifies the origin airport (FROM) or the CO RTE, the reference coordinates on MCDU IRS INIT page are reset to the airport reference point (extracted from the FMS database). The pilot may also manually modify these coordinates.
If the MCDU coordinates change, when the ADIRS are already in NAV mode, the ALIGN ON REF prompt is displayed : Crosscheck the reference coordinates on MCDU IRS INIT page against the IRS position on the MCDU POSITION MONITOR page.

When the GPS is available, or for flights in good radio navigation coverage airspace, initialize the ADIRS to the airport reference point extracted from the FMS database. This reduces the risk of entering incorrect values.
If the GPS is not available, and long segments in poor radio navaid coverage airspace are expected, initialize the ADIRS to the gate coordinates. This increases the accuracy of the ADIRS position computation.
If the airport reference point is not stored in the FMS database, and the gate coordinates are not available, use the airport reference point coordinates from the airport chart.

ALIGN ON REF prompt.....PRESS and CONFIRM

The reference coordinates on MCDU IRS INIT page are sent to the ADIRS, and their navigation starting point is set.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

ALIGNMENT/INITIALIZATION ERROR

The ADIRS keeps a record of the last position it had the last time it was in NAV mode. It is also able to estimate the present latitude after a complete alignment. The ADIRS may use this information to detect coarse initialization errors.
If the ADIRS alignment or initialization is not correct, the ALIGN light will flash. If any of the 3 ADIRS indicates an alignment error, the prompt REALIGN IRS appears on the INIT page (instead of ALIGN IRS).

- **If the IR FAULT light flashes:**

  The affected ADIRS can only be used in ATT mode.

- **If the ALIGN light flashes before the alignment phase is completed:**

  DISPLAY DATA switch.....STS

  If the CDU does not display any message, the position sent to the ADIRS disagrees with the last memorized position, or with the ADIRS estimated latitude. Check the initialization position, and reenter it.
  If the CDU displays a message, take the appropriate action.

- **If the ALIGN light flashes at the end of the alignment phase:**

  Check the ALIGN IRS prompt on the MCDU. If it is present, press it to initialize the ADIRS.

  - **If the REALIGN IRS prompt is present:**

    The position sent to the ADIRS disagrees with the last memorized position, or with the ADIRS estimated latitude.

    ADIRS.....PERFORM FAST ALIGNMENT
    POSITION INITIALIZATION.....CHECK & ENTER AGAIN

    If the ALIGN light still flashes, perform a complete alignment of the affected ADIRS.

Applicable to: B-HSO, B-HSP

ALIGNMENT/INITIALIZATION ERROR

The ADIRS keeps a record of the last position it had the last time it was in NAV mode. It is also able to estimate the present latitude after a complete alignment. The ADIRS may use this information to detect coarse initialization errors.
If the pilot manually initializes the ADIRS, and a GPS position is available, the GPS position is used to crosscheck the pilot entry.
If any of the 3 ADIRS indicates an alignment error, the prompt REALIGN IRS appears on the INIT page (instead of ALIGN IRS).

- **If the IR FAULT light flashes:**

  The affected ADIRS can only be used in ATT mode.

Applicable to: B-HSQ, B-HSR

ALIGNMENT/INITIALIZATION ERROR

The ADIRS keeps a record of the last position it had the last time it was in NAV mode. It is also able to estimate the present latitude after a complete alignment. The ADIRS may use this information to detect coarse initialization errors.
If the pilot manually initializes the ADIRS, and a GPS position is available, the GPS position is used to crosscheck the pilot entry.
If any of the 3 ADIRS detects an alignment or initialization error, the prompt ALIGN ON REF is displayed on the IRS INIT page. If the flight crew has previously entered a REF position and the MCDU scratchpad messages REF/GPS POS DIFF or REF/LAST IRS POS DIFF are displayed, the flight crew has to reenter the REF position. When the REF position is entered again, the prompt ALIGN ON REF is displayed on the IRS INIT page.

- **If the IR FAULT light flashes:**

  The affected ADIRS can only be used in ATT mode.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

SHUTDOWN

Mode selectors.....OFF

Pull and turn the 3 mode selectors to OFF.
The message screen displays REALN DESN 5 s (realign decision) for 5 s, then a 5 s countdown to off (OFF TIME 5 s displayed). Flight crew must not pull the circuit breakers until the final countdown is completed.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

STATUS MESSAGES

Status messages appear, when the DISPLAY DATA switch is set to STS. If there is more than one condition calling for a message, the display scrolls to the next message every 2 s.

MESSAGE	DESCRIPTION
STS IR FAULT	Hard failure. Select ATT (if corresponding message is displayed) or refer to MMEL or remove ADIRU for maintenance.
STS-DELAY MAINT	Failure not affecting IR functioning. Service ADIRU when convenient.
STS-ENTER PPOS	Enter present position or check entered position is correct. *Note: The confirmation of an erroneous longitude at the present position entry will create a wrong position of the aircraft symbol on the NDs.*
STS-SELECT ATT	Hard IRU failure, select ATT mode.
STS-EXCESS MOTION	Excess motion detected during alignment. ADIRU will automatically restart alignment. Ensure aircraft is not moving.
STS-SWITCH ADR	ADR invalid.
STS-CHECK CK/BK	Check circuit breakers (1)
STS-CDU FAULT	Remove CDU for maintenance.
STS-ENT MAG HDG	Enter magnetic heading.

(1) *If a corresponding FAULT light comes on, check BAT 1 load.*

TCAS

Applicable to: ALL

GENERAL

For System Description, *Refer to DSC-34-80-10 General*.
For Operational Procedures, *Refer to PRO-ABN-34 TCAS WARNINGS*.
Refer to Part A 8.3.1.4 Policy and Procedures for the use of TCAS.

CONFLICT RESOLUTION PRINCIPLES

- **Traffic Advisory (TA)**
  If an intruder represents a potential collision threat, a visual and aural Traffic Advisory will be given. This advisory helps the crew to visually situate the intruder. It also prepares the crew for a possible Resolution Advisory. However, not every RA is preceded by a TA.
- **Resolution Advisory (RA)**
  If the intruder is considered to be a real collision threat, an aural and visual Resolution Advisory is given.
  TCAS determines the optimum vertical maneuver that ensures effective separation, with a minimum change in vertical speed.

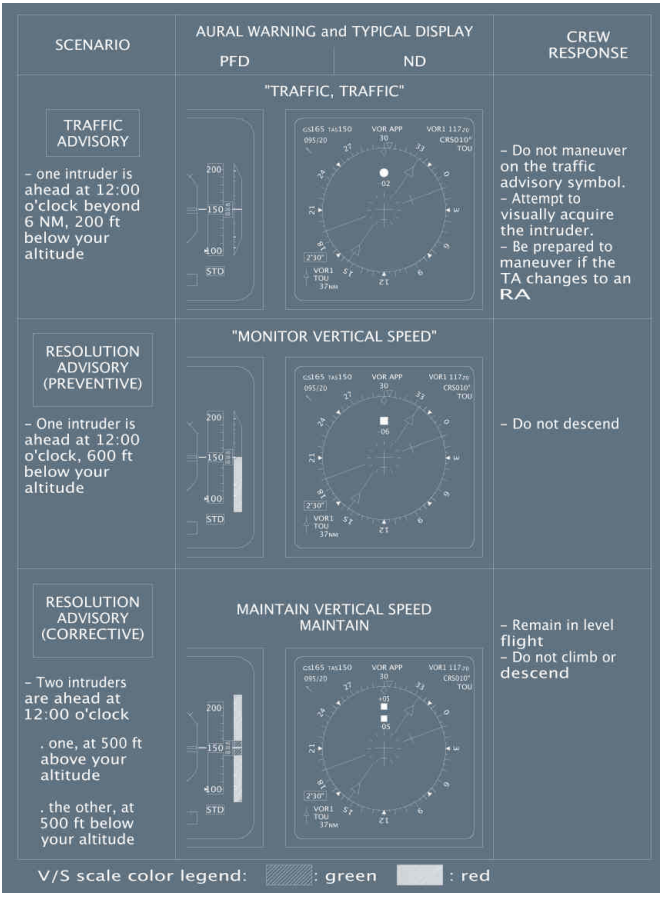
  Depending on each situation, TCAS generates a :
  - Preventive Advisory (i.e. the actual vertical speed may be maintained). It displays the vertical speed range to be avoided.
  - Corrective Advisory i.e. the actual vertical speed is within the range to be avoided and a recommended vertical speed (fly to) range is displayed.
  - Modified Corrective Advisory, which changes already displayed RA (i.e if the intruder changes their vertical speed).

OPERATIONAL RECOMMENDATIONS

- **Avoidance generalities:**
  Always follow the RAs orders, even if they lead to cross the altitude of the intruders, as they ensure the best global separation.

CAUTION	If a pilot does not follow a RA, he should be aware that the intruder may be TCAS equipped and may be maneuvering toward his aircraft in response to a coordinated RA. This could compromise safe separation.

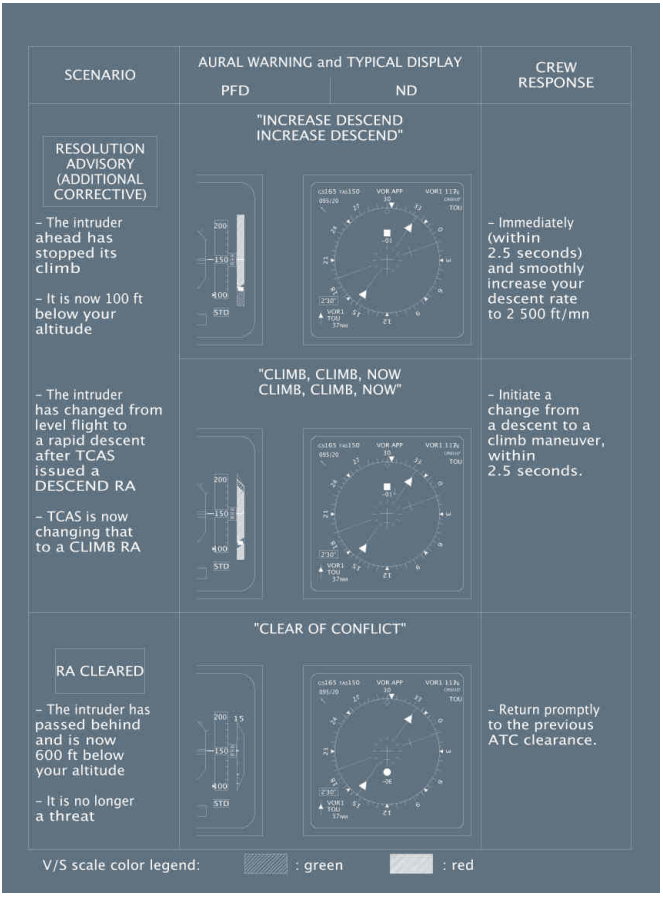
  Pilots should comply with the vertical speed limitations during the last 2 000 ft of climb or descent. In particular, pilots should limit vertical speeds to 1 500 ft/min during the last 2 000 ft of a climb or descent, especially when they are aware of traffic that is converging in altitude and intending to level off 1 000 ft feet above or below the pilot's assigned altitude.
- **Select TA only mode in the following cases:**
  - Engine failure.
  - Dispatch with landing gear down (if applicable).
  - At particular airports and during particular procedures identified by an operator as having a significant potential for unwanted a inappropriate RAs (closely-spaced parallel runways, converging runways, low terrain along the final approach...)



SCENARIO
AURAL WARNING and TYPICAL DISPLAY
PFD
ND
CREW RESPONSE
"TRAFFIC, TRAFFIC"
TRAFFIC ADVISORY
- one intruder is ahead at 12:00 o'clock beyond 6 NM, 200 ft below your altitude
- Do not maneuver on the traffic advisory symbol.
- Attempt to visually acquire the intruder.
- Be prepared to maneuver if the TA changes to an RA
"MONITOR VERTICAL SPEED"
RESOLUTION ADVISORY (PREVENTIVE)
- One intruder is ahead at 12:00 o'clock, 600 ft below your altitude
- Do not descend
MAINTAIN VERTICAL SPEED
MAINTAIN
RESOLUTION ADVISORY (CORRECTIVE)
- Two intruders are ahead at 12:00 o'clock
. one, at 500 ft above your altitude
. the other, at 500 ft below your altitude
- Remain in level flight
- Do not climb or descend
V/S scale color legend: : green : red

SCENARIO	AURAL WARNING and TYPICAL DISPLAY PFD | ND	CREW RESPONSE
RESOLUTION ADVISORY (CORRECTIVE) - The intruder is ahead at 12:00 o'clock, 400 ft above your altitude - You are already climbing at 2000 ft/mn	"ADJUST VERTICAL SPEED ADJUST" 	- Adjust vertical speed so as to be in the green area of the PFD's speed scale by reducing climb vertical speed as appropriate
- The intruder is ahead at 12:00 o'clock, 200 ft below your altitude	"CLIMB, CLIMB" 	- Promptly (within 5 seconds) smoothly establish a climb rate of 1 500 ft/mn
- The intruder is ahead at 12:00 o'clock, 200 ft above your altitude	"DESCEND, DESCEND" 	- Promptly (within 5 seconds) and smoothly establish a descent rate of 1 500 ft/mn

V/S scale color legend: : green : red



APPROACH ON PAPI OR TVASI

Applicable to: ALL

Eye to wheel height on approach is 25 ft and minimum recommended wheel clearance over the threshold is 20 ft. Do not follow Precision Approach Path Indicator (PAPI) or "T"-Visual Approach Slope Indicator (TVASI) guidance below 200 ft when PAPI or TVASI Minimum Eye Height over Threshold (MEHT) is less than 45 ft.

QFE USE FOR TO/APPR/LDG ON AIRCRAFT WITH QNH ONLY PIN PROGRAMMING

Applicable to: ALL

The crew should not use QFE on aircraft with a “QNH only” pin programming (incorrect profile computation of the managed vertical modes CLB, DES and FINAL APPR, possible false GPWS warnings in mountainous areas).

ENHANCED GROUND PROXIMITY WARNING SYSTEM (EGPWS)

Applicable to: ALL

The Flight Management System (FMS) provides aircraft position inputs to the EGPWS for enhanced function processing purpose.
The TERR pb-sw located on the overhead panel enables the activation or deactivation of the enhanced functions of the EGPWS.
If the TERR ON ND is not selected, and a terrain alert is generated, the terrain is automatically displayed on the ND.
The brightness of the terrain indication on the ND is controlled via the weather radar brightness control knob. If the weather radar brightness was set to low (due to bad weather) and a terrain alert occurs, then the terrain display brightness will also be low.
Therefore, when a terrain alert occurs, the ND weather/terrain image brightness may need to be adjusted.

CLOCK

Applicable to: ALL

CLOCK ADJUSTMENT

For guidelines on adjustment procedures, refer to DSC-31-55-20.

If the clock requires adjustment , the following time references may be used:

- For MNPS Navigation (Minimum Navigation Performance Specification) an accurate UTC time check should be completed. This may be done by using:
  - WWV - National Institute Of Standards (NIST - Fort Collins, Colorado). WWV operates continually H24 on 2,500, 5,000, 10,000, 15,000 and 20,000 kHz
  - CHU - National Research Council (NRC - Ottawa, Canada) - CHU operates H24 on 3,330, 7,335 and 14,670 kHz (SSB).
  - BBC - British Broadcasting Corporation (United Kingdom). Details in Volume 5.
  - Or any other suitable means.

SPECIALIZED MEANS OF NAVIGATION REQUIREMENTS

Applicable to: ALL

GENERAL

Certain routes may be listed in MEL 01-34 which cross areas designated in Schedule 8 of the Air Navigation (Hong Kong) Order, 1995. Navigation within these areas is dictated by a minimum list of equipment, detailed in the MEL under Specialized Means of Navigation Sectors (SMNS). Normal navigation is accomplished with the use of the FMGS. When available, the aircraft's position should be monitored with reference to radio navigation facilities.

MINIMUM SERVICEABLE EQUIPMENT

The minimum serviceable equipment for all designated SMNS will be listed in MEL 01-34. For all the routes designated in MEL 01-34, the equipment specified is to be operable at the outbound gateway.

GATEWAY

This is the term given to a recognized exit/entry point with defined coordinates and with fixing capability over which aircraft are normally re-routed from/to an area requiring Specialized Means of Navigation.

SCHEDULE 8 NAV AREAS

Applicable to: ALL

SPECIAL PROCEDURES

These instructions apply to all flights within areas specified in Schedule 8 of the AN(HK)O which fall in Dragonair's AOC region, Part A 8.3.1.2 refers.

NAVIGATION EQUIPMENT PROCEDURES

In general the aircraft is to be operated in accordance with the Long Range Navigation procedures of PRO-SPO-40.

IN FLIGHT

If any part of the FMGS or navigation equipment becomes unserviceable to the extent it may affect the accuracy of the navigation, before entering a Schedule 8 area, then the Commander is to divert to a suitable alternate outside the Schedule 8 area.

PRE DEPARTURE – LEAVING A SCHEDULE 8 AREA

Normal provisions of the MEL apply.

UNRELIABLE NAVIGATION CAPABILITY

If the navigation equipment in the aircraft or on the ground becomes unreliable, or a large discrepancy becomes apparent whilst in a Schedule 8 Area, the Commander is to:

- Advise ATC of the degraded navigational capability.
- Adopt a course of action that will ensure the aircraft is navigated to an area where normal navigation can be resumed as expeditously as possible.

Intentionally left blank

INADVERTENT OXYGEN MASK DEPLOYMENT

Applicable to: ALL

If the oxygen masks drop inadvertently, and

- **If the oxygen masks have been pulled down and oxygen flow has been activated (oxygen generator condition indicator is normally yellow; it turns black after activation):**
  - The passenger(s) in that row should be reseated to vacant passenger seat(s) if possible.
  - The masks are not to be re-stowed in the PSU.
  - The PSU is to be left open and the tubing of the oxygen masks taped to the PSU compartment/ceiling of the aircraft.
  - Any passenger who could not be reseated must be given a portable oxygen bottle and briefed on its use in case of decompression.
- **If the oxygen masks have not been pulled down and oxygen flow has not been activated (oxygen generator condition indicator is normally yellow; it turns black after activation):**
  - The passenger(s) in that row should be reseated to vacant passenger seat(s) if possible.
  - The masks are not to be re-stowed in the PSU.
  - The PSU is to be left open and the tubing of the oxygen masks taped to the PSU compartment/ceiling of the aircraft.
  - Any passenger who could not be reseated must be able to reach the taped masks should oxygen be subsequently required.
- **An AML entry must be made to ensure that maintenance action is undertaken.**

Intentionally left blank

USE OF CFDS FOR DISPATCH

Applicable to: ALL

GENERAL

The purpose of this chapter is to provide procedures for use by CFDS qualified flight crew at stations where no suitably qualified maintenance personnel are available.
These CFDS procedures provide an alternative but complementary method for completing the corresponding Maintenance Procedure as described in the MEL.
Cathay Pacific Engineering must be consulted and will have the final say as to whether the aircraft may be dispatched.

The following MUST be complied with when using CFDS procedures:

- Both engines must be shut down and the Park Brake SET,
- One pilot is to read the procedures while the other pilot uses the MCDU,
- Only one MCDU should be used at a time or a 'TIME OUT' message will appear in the scratch pad,
- When using the RETURN line select key (LSK 6L), pause after each selection until the 'WAIT FOR SYSTEM RESPONSE' message in the scratch pad has cleared. It sometimes takes a few seconds for the system components to reconnect whilst the CFDS facility extracts itself from deep inside a complex system. If the RETURN key is selected too quickly, or the MCDU p/b is pressed, the various system components may not reconnect correctly - in which case the aircraft must be de-powered completely to reset all the on board systems,
- A Maintenance Log entry must be made by the flight crew. If the unserviceability subsequently clears itself then a "FOR INFO" entry is sufficient. If the unserviceability remains then the Aircraft Maintenance Log must be completed as per Ops Part A 8.6.1,
- Cathay Engineering must be consulted prior to dispatch,
- Dispatch using the CFDS procedures must be recorded on the CAR. Refer to Ops Part A 8.6.1.19.

These procedures may be used when one of the following defects is present.

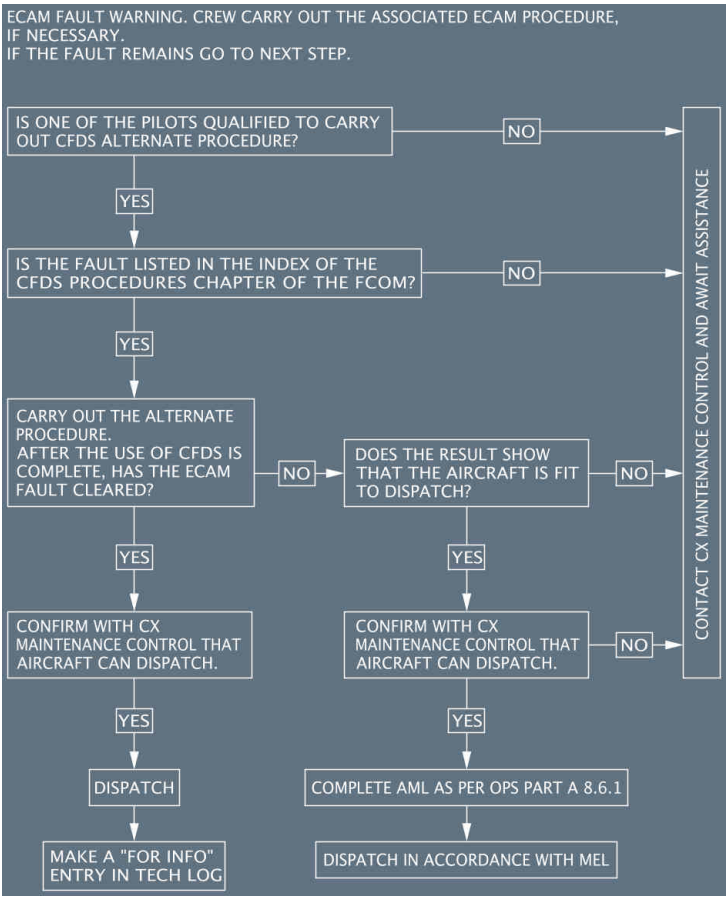
15. Red down arrow light on landing gear selector panel	Test of the L/G GEAR NOT DOWN ECAM warning	PRO-SUP-45 15. Test of the L/G GEAR NOT DOWN ECAM warning	MEL/MI-32-61-02A

Note: For the initial issue of PRO-SUP-45 and all subsequent revisions by Airbus Industrie, approval must first be obtained from HDA and CPA Engineering in accordance with EOMP 14–9 of the amendments prior to PRO-SUP-45 issuance by Airbus Industrie.

GENERALIZED FLOW CHART FOR USE IN CONJUNCTION WITH PRO–SUP–45 PILOT APPROVED PROCEDURES



1. IDG FUEL RECIRCULATION TEST

Applicable to: ALL

In the event of an ECAM warning ELEC GEN 1(2) FAULT or ELEC IDG 1(2) OIL LOPR/OVHT, the following procedure is used to check the IDG of the operational generator:

1. Energize the aircraft.

2. Refer to MEL/MI-24-22-01A AC Main Generation (IDG, GCU, Line Contactor) and check that the items listed under paragraphs 3), 4), 7), 8) and 9) are operative and the limitation listed under paragraphs 1), 2) and 5) can be complied with.

The item listed under paragraph 6) is covered by continuing below.
- If engine generator 1 is operational, go to step 3.
- If engine generator 2 is operational, go to step 6.

ENGINE GENERATOR 1 OPERATIONAL

3. On the panel 50 VU, release the ENG FADEC GND POWER 1 (ON legend illuminated).

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L)	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L)	SYSTEM REPORT/TEST page appears.
Press NEXT PAGE P/B.	Second SYSTEM REPORT/TEST page appears.
Select ENG line key (LSK 1R).	SYSTEM REPORT/TEST ENG page appears.
Select FADEC 1 A line key (LSK 2L).	FADEC 1A menu page appears.
Select LAST LEG REPORT line key (LSK 1L)	FADEC 1A LAST LEG REPORT page appears. Check if any of the following failure messages are displayed: - ACOC OIL TEMP TC/HC/EEC 1 - IDG OIL TEMP TC/HC/EEC 1 - ACOC AIR MOD VLV/HC/EEC 1 - FUEL DIV RET VLV/HC/EEC 1 - HMS FUEL OVTMP 1 - HMS ENG OIL OVTMP 1 - HMS IDG OIL OVTMP 1 - HMS IDG OVTMP W/RECIRC 1 - FUEL DIV RET VLV/EEC 1. If one or more of these messages are displayed maintenance is required – NO DISPATCH.
Select RETURN line key twice (LSK 6L).	SYSTEM REPORT/TEST ENG page appears.
Select FADEC 1B line key (LSK 2R).	FADEC 1B page appears.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select LAST LEG REPORT line key (LSK 1L)	FADEC 1B LAST LEG REPORT page appears. Check if any of the following failure messages are displayed: - ACOC OIL TEMP TC/HC/EEC 1 - IDG OIL TEMP TC/HC/EEC 1 - ACOC AIR MOD VLV/HC/EEC 1 - FUEL DIV RET VLV/HC/EEC 1 - HMS FUEL OVTMP 1 - HMS ENG OIL OVTMP 1 - HMS IDG OIL OVTMP 1 - HMS IDG OVTMP W/RECIRC 1 - FUEL DIV RET VLV/EEC 1. If one or more of these messages are displayed maintenance is required – NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
PressMCDU MENU key.	MCDU MENU page appears.

4. On the panel 50VU, push the ENG 1 FADEC GND PWR pb-sw (ON legend extinguished).
5. Go to step 8.

ENGINE GENERATOR 2 OPERATIONAL

6. On the panel 50 VU, release the ENG 2 FADEC GND POWER pb-sw (ON legend illuminated).

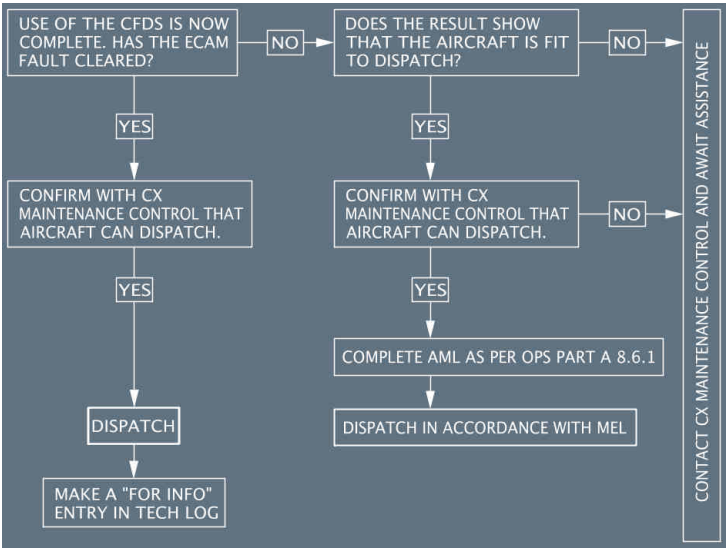
ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU menu page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Press NEXT PAGE P/B.	Second SYSTEM REPORT/TEST page appears.
Select ENG line key(LSK 1R).	SYSTEM REPORT/TEST ENG page appears.
Select FADEC 2A line key (LSK 3L).	FADEC 2A page appears.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select LAST LEG REPORT line key (LSK 1L)	FADEC 2A LAST LEG REPORT page appears. Check if any of the following failure messages are displayed: - ACOC OIL TEMP TC/HC/EEC 2 - IDG OIL TEMP TC/HC/EEC 2 - ACOC AIR MOD VLV/HC/EEC 2 - FUEL DIV RET VLV/HC/EEC 2 - HMS FUEL OVTMP 2 - HMS ENG OIL OVTMP 2 - HMS IDG OIL OVTMP 2 - HMS IDG OVTMP W/RECIRC 2 - FUEL DIV RET VLV/EEC 2. If one or more of these messages are displayed maintenance is required – NO DISPATCH.
Select RETURN line key twice (LSK 6L).	SYSTEM REPORT/TEST ENG page appears.
Select FADEC 2B line key (LSK 3R)	FADEC 2B page appears.
Select LAST LEG REPORT line key (LSK 1L)	FADEC 2B LAST LEG REPORT page appears. Check if any of the following failure messages are displayed: - ACOC OIL TEMP TC/HC/EEC 2 - IDG OIL TEMP TC/HC/EEC 2 - ACOC AIR MOD VLV/HC/EEC 2 - FUEL DIV RET VLV/HC/EEC 2 - HMS FUEL OVTMP 2 - HMS ENG OIL OVTMP 2 - HMS IDG OIL OVTMP 2 - HMS IDG OVTMP W/RECIRC 2 - FUEL DIV RET VLV/EEC 2. If one or more of these messages are displayed maintenance is required – NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

7. On the panel 50 VU, push the ENG 2 FADEC GND PWR pb-sw (ON legend extinguished).
8. Check the applicable MEL Operational Procedures have been complied with then exit the procedure using the flow chart below.



2. GALLEY SUPPLY SYSTEM LOADS DISCONNECTION

Applicable to: ALL

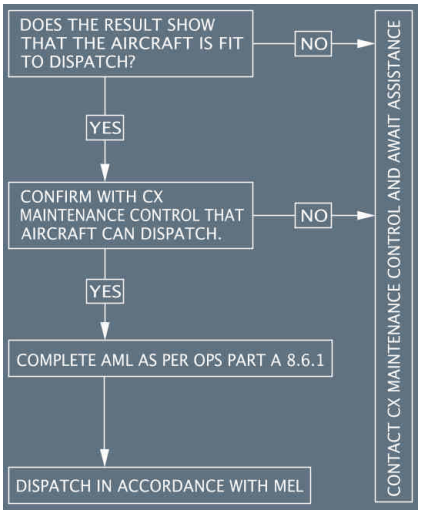
In the event of an ECAM warning ELEC GEN 1(2) OVERLOAD or ELEC APU GEN OVERLOAD, completion of the ECAM actions would normally clear the warning. If the ECAM warning remains displayed, then both the automatic and the manual load shed systems are inoperative, and the following procedure must be used to de-energize the galleys before the aircraft can be dispatched.

1. Energize the aircraft.
2. Open the following circuit breakers.

FIN	DESIGNATION	LOCATION
1XA	ELEC/GALLEY/CTL	122 VU 26S
7MC	ELECT/GALLEY/CNTOR	122 VU 28S
3MC	MAIN GALLEY A	123 VU 04AF
12MC	GALLEY B ◁	123 VU 09AD
1MC	MAIN GALLEY C or FWD &AFT GALLEY	123 VU 10AE or 3AE
2MC	GALLEY D	123 VU 04AD or 2AE
14MC	MAIN GALLEY E	123 VU 09AF
16MC	MAIN GALLEY F	123 VU 10AC

3. On the panel 35 VU, release the GALLEY pb-sw (OFF legend illuminated).

4. Check no power is available to any of the galley equipment by going to the galleys and attempting to switch on the galley systems.
5. Dispatch the aircraft with the above circuit breakers open and with the GALLEY pb-sw in the OFF position (OFF legend illuminated).
6. There are no applicable MEL Operational Procedures or limitations. Exit the procedure using the flow chart below.



3. RUDDER PEDAL TRANSDUCER FAILURE CONFIRMATION

Applicable to: ALL

In the event of an ECAM warning F/CTL AIL SERVO FAULT, the following procedure is used to check if the fault is caused by the rudder pedal transducer.

1. Energize the aircraft.
2. Make sure that the following C/B are closed.

FIN	DESIGNATION	LOCATION
15CE1	FLIGHT CONTROLS/ELAC 1/NORM/SPLY	49 VU 11B
20CE1	FLIGHT CONTROLS/FCDC 1/SPLY	49 VU 10B
21CE1	FLIGHT CONTROLS/SEC 1/NORM/SPLY	49 VU 08B
2TW	CFDS/CFDIU/SPLY	121 VU 18J
8TW	CFDS/CFDIU/BACK-UP	121 VU 17J
20CE2	FLIGHT CONTROLS/FCDC 2/SPLY	121 VU 20Q

Continued on the following page

Continued from the previous page

FIN	DESIGNATION	LOCATION
21CE3	FLIGHT CONTROLS/SEC 3/SPLY	121 VU 19Q
21CE2	FLIGHT CONTROL/SEC 2/SPLY	121 VU 18Q
15CE2	FLIGHT CONTROLS/ELAC 2/NORM/SPLY	121 VU 20R
16CE1	FLT CTL/ELAC 1 pb/STBY/SPLY	105 VU 01AS
16CE2	FLT CTL/ELAC 2 pb/STBY/SPLY	105 VU
22CE	FLT CTL/SEC 1/STBY/SPLY	105 VU

Note: Circuit breaker panel 105 VU is located in the avionics compartment under the cockpit floor.

3. On the panel 23 VU check that the ELAC 1 pb and SEC 1 pb are pressed in (FAULT and OFF legends extinguished).
4. On the panel 24 VU check that the ELAC 2 pb, SEC 2 pb and SEC 3 pb are pressed in (FAULT and OFF legends extinguished).
5. Select ADIRS 1, 2 and 3 to the NAV position.
6. Do the following procedure:

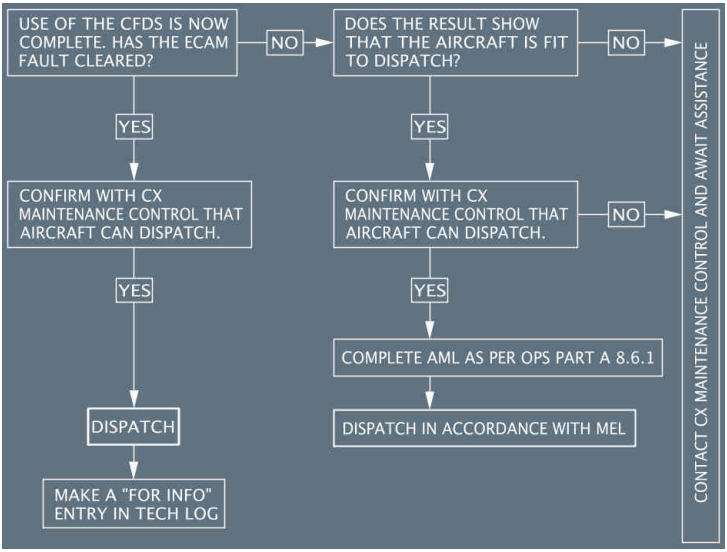
ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU menu page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select EFCS 1 line key (LSK 1L).	EFCS 1 page appears.
Select GROUND SCAN line key (LSK 4L).	EFCS 1 GROUND SCAN page appears with this message displayed: - START GROUND SCAN - WAIT 2 MINUTES - STOP GROUND SCAN <START GROUND SCAN STOP> <GROUND REPORT>
Select START GROUND SCAN key (LSK 4L)	The page disappears and comes up again *Note: The same page is displayed without any complementary information about the test progress.*
Wait for 2 min minimum.	
Select GROUND SCAN STOP line key (LSK 4R).	The page disappears and comes up again.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select the GROUND REPORT line key (LSK 5L)	EFCS 1 GROUND REPORT page appears. 1. Check the following messages are displayed: - NO FAULTS RECORDED ! or - RUDDER PEDAL XDCR ● **If the above ″RUDDER PEDAL XDCR″ message is displayed by itself then the aircraft can be dispatched as is.** ● **If there are any other failure messages present maintenance is required - NO DISPATCH.**
Select RETURN line key (LSK 6L) until the CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

7. Check the applicable MEL Operational Procedures have been complied with then exit the procedure using the flow chart below.



4. SFCS 1 FLAP CHANNEL TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL FLAP SYS 2 FAULT the following procedure is used to check the SFCS 1 flap channel and its associated Wing Tip Brake solenoids.

1. Energize the aircraft
2. *Refer to MEL/MI-27-51 SFCC Flap Channel* and check the items listed under paragraph 3) are operative. The requirements listed under paragraphs 1), 2), are covered by continuing below.

SFCC 1 TEST PROCEDURE

3. Do the following procedure:

ACTIONS	RESULTS
On the RH or LH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu appears.
Select SYSTEM REPORT/TEST line key (LSK 5L)	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R)	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 1 line key (LSK 3L)	SFCC-1 page appears.
Select SYSTEM STATUS FLP line key (LSK 4R)	SFCC-1 SYSTEM STATUS FLP page appears 1. Check the following messages are displayed: - NO FAULTS or - SLT 1 NO SFCC 2 DATA and/or - FLP 1 NO SFCC 2 DATA ● **If there are any other failure messages present maintenance is required - NO DISPATCH.**
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 2 line key (LSK 4L).	SFCC-2 page appears.
Select SYSTEM STATUS FLP line key (LSK 4R).	SFCC-2 SYSTEM STATUS FLP page appears. 1. Check for the following message: - FLP SYS LOCKED

- *If the message "FLP SYS LOCKED" is present, SFCC 2 has applied the Wing Tip Brakes and they have to be reset, go to step 4 (See step 4).*
- *If there is no "FLP SYS LOCKED" message go to step 7 (See step 7).*

WTB RESET PROCEDURE

4. Do the following procedure:

Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 2 line key (LSK 4L).	SFCC-2 page appears.
Press NEXT PAGE key	Second SFCC-2 page appears.
Select TEST/RESET FLP line key (LSK 1R).	SFCC-2 FLAP TEST/RESET page appears.
Select WTB-RESET line select key (LSK 1R).	SFCC-2 FLAP WTB-RESET instructions page appears.

CAUTION	CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.

Select START WTB RESET line select key (LSK 5L).	SFCC-2 FLAP WTB-RESET PERFORMED message appears.

5. Open the following circuit breaker:

FIN	DESIGNATION	LOCATION
8CV	FLIGHT CONTROLS/FLP/CTL AND MONG/SYS 2	121 VU Q21

Select RETURN line key (LSK 6L) once.	SFCC-2 FLAP TEST/RESET page appears.

Note: If the ECAM warning F/CTL FLAPS LOCKED is still present after performing the WTB reset procedure a mechanical failure of the slat system may have occurred. NO DISPATCH.

6. Go to step 7 (See step 7).

SFCC 1 FLAP WTB TEST PROCEDURE

7. Do the following procedure:

Note: Paragraph 2) under MEL reference 27-51-01A requires the SFCC 1 WTB's operation to be confirmed by test before each flight.

8. On the panel 50 VU, push the BLUE PUMP OVRD pb-sw (ON legend illuminated)
9. On the panel 40 VU, push the YELLOW ELEC PUMP pb-sw (ON legend illuminated)

Note: Wait until the hydraulic power has stabilized before entering CFDS.

10. Open the following circuit breakers:

FIN	DESIGNATION	LOCATION
7CV	FLIGHT CONTROLS/SLT/CTL/SYS 2	121 VU R21
8CV	FLIGHT CONTROLS/FLP/CTL AND MONG/SYS 2	121 VU Q21

CAUTION	*CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.*

11. Set the flap lever to position 3; the slats and flaps move to position 3.
12. Do the following procedure:

ACTIONS	RESULTS
Select RETURN line key (LSK 6L) twice	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 1 line key (LSK 3L).	SFCC-1 page appears.
Press NEXT PAGE key	Second SFCC-1 page appears.
Select TEST/RESET FLP line key (LSK 1R).	SFCC-1 FLAP TEST/RESET page appears.
Select WTB/POB TEST line key (LSK 2L).	SFCC-1 FLAP WTB/POB TEST instructions page appears.

Continued on the following page

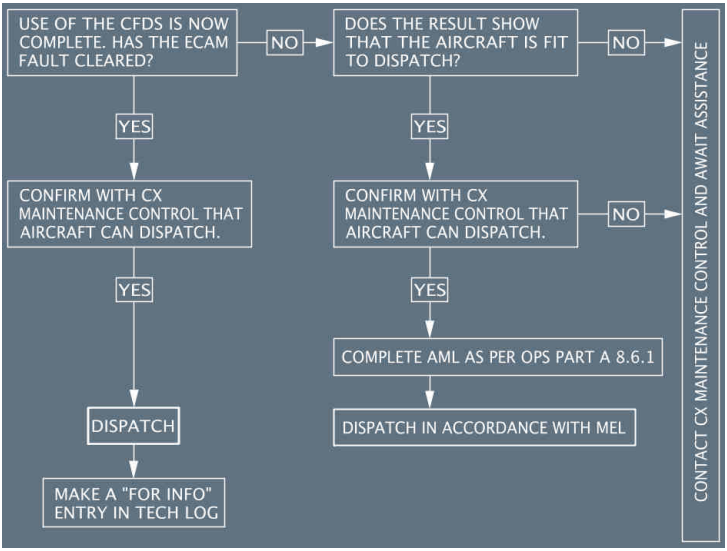
Continued from the previous page

ACTIONS	RESULTS
Select CONTINUE line key (LSK 5L).	Second SFCC-1 FLAP WTB/POB TEST instructions page appears. Note: *The page normally flashes on and off periodically.*
Select START TEST line key (LSK 5L).	SFCC-1 FLAP WTB/POB TEST IN PROGRESS message appears. 1. Check that the following message is displayed within approximately 2 min, otherwise - NO DISPATCH: PERFORMED NO FAULTS Note: *If the test is unsuccessful after 3 attempts ("CFDS TEST INVALID"), try another test with a ground power cart connected, or with the engine driven hydraulic pumps on, and cranking the related engine 2.*
Select RETURN line key (LSK 6L) until the CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU appears.

13. Close circuit breaker 7 CV (121 VU R21)

Note: *Circuit breaker 8CV (121 VU Q21) remains tripped for DISPATCH.*

14. Set the flap lever to position 0, the slats and flaps move to position 0.
15. On the panel 50 VU, release the BLUE PUMP OVRD pb-sw (ON legend extinguished).
16. On the panel 40 VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguished)
17. Check the applicable MEL limitations have been complied with then exit the procedure using the flow chart below.



5. SFCS 1 SLAT CHANNEL TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL SLAT SYS 2 FAULT the following procedure is used to check the SFCC 1 slat channel and its associated Wing Tip Brake solenoids.

1. Energize the aircraft
2. *Refer to MEL/MI-27-51 SFCC Slat Channel* and check the items listed under paragraph 3) are operative. The requirements listed under paragraphs 1), 2), are covered by continuing below.

SFCC 1 TEST PROCEDURE

3. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key	MCDU menu page appears.
Select CFDS line key (LSK 4L)	CFDS main page menu appears.
Select SYSTEM REPORT/TEST line key (LSK 5L)	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears
Select SFCC 1 line key (LSK 3L).	SFCC-1 page appears.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select SLT SYSTEM STATUS line key (LSK 4L)	SFCC-1 SYSTEM STATUS SLT page appears 1. Check the following messages are displayed: - NO FAULTS or - SLT 1 NO SFCC 2 DATA. ● **If there are any other failure messages present maintenance is required - NO DISPATCH.**
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 2 line key (LSK 4L).	SFCC-2 page appears.
Select SLT SYSTEM STATUS line key (LSK 4L).	SFCC-2 SYSTEM STATUS SLT page appears. 1. Check for the following messages: - SLT SYS LOCKED

- If the message “SLT SYS LOCKED” is present, SFCC 2 has applied the Wing Tip Brakes and they have to be reset, See step 4.
- If there is no “SLT SYS LOCKED” message See step 7.

WTB RESET PROCEDURE

4. Do the following procedure:

Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 2 line key (LSK 4L).	SFCC-2 page appears.
Press NEXT PAGE key.	Second SFCC-2 page appears.
Select SLT TEST/RESET line key (LSK 1L).	SFCC-2 SLAT TEST/RESET page appears.
Select WTB-RESET line select key (LSK 1R).	SFCC-2 SLAT WTB-RESET instructions page appears.

CAUTION	CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.

Select START WTB RESET line select key (LSK 5L).	SFCC-2 SLAT WTB-RESET PERFORMED message appears.

5. Open, secure and tag, the following circuit breaker:

FIN	DESIGNATION	LOCATION
7CV	FLIGHT CONTROLS/SLT/CTL/SYS 2	121 VU R21

Select RETURN line key (LSK 6L) once.	SYSTEM REPORT/TEST F/CTL page appears.

Note: If the ECAM warning F/CTL SLATS LOCKED is still present after performing the WTB reset procedure a mechanical failure of the slat system may have occurred. NO DISPATCH.

6. Go to step 7 (See step 7).

SFCC 1 SLAT WTB TEST PROCEDURE

7. Do the following procedure :

Note: Paragraph 2) under MEL reference 27-51-01B requires the SFCC 1 WTB's operation to be confirmed by test before each flight.

8. On the panel 50 VU, push the BLUE PUMP OVRD pb-sw (ON legend illuminated).
9. On the panel 40 VU, push the YELLOW ELEC PUMP pb-sw (ON legend illuminated).

Note: Wait until hydraulic power has stabilized before entering CFDS.

10. Open the following circuit breakers:

FIN	DESIGNATION	LOCATION
7CV	FLIGHT CONTROLS/SLT/CTL/SYS 2	121 VU R21
8CV	FLIGHT CONTROLS/FLP/CTL AND MONG/SYS 2	121 VU Q21

CAUTION	CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.

11. Set the flap lever to position 3 ; the slats and flaps move to position 3.
12. Do the following procedure:

ACTIONS	RESULTS
Select RETURN line key (LSK 6L) twice	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 1 line key (LSK 3L).	SFCC-1 page appears.
Press NEXT PAGE key.	Second SFCC-1 page appears.
Select SLT TEST/RESET line key (LSK 1L).	SFCC-1 SLAT TEST/RESET page appears.
Select WTB/POB TEST line key (LSK 2L).	SFCC-1 SLAT WTB/POB TEST instructions page appears.
Select CONTINUE line key (LSK 5L).	Second SFCC-1 SLAT WTB/POB TEST instructions page appears. *Note: The page normally flashes on and off periodically.*
Select START TEST line key (LSK 5L).	SFCC-1 SLAT WTB/POB TEST IN PROGRESS message appears. 1. Check that the following message is displayed within approximately 2 min, otherwise - NO DISPATCH: PERFORMED NO FAULTS *Note: If the test is unsuccessful after 3 attempts ("CFDS TEST INVALID"), try another test with a ground power cart connected, or with the engine driven hydraulic pumps on, and cranking the related engine 2.*

Continued on the following page

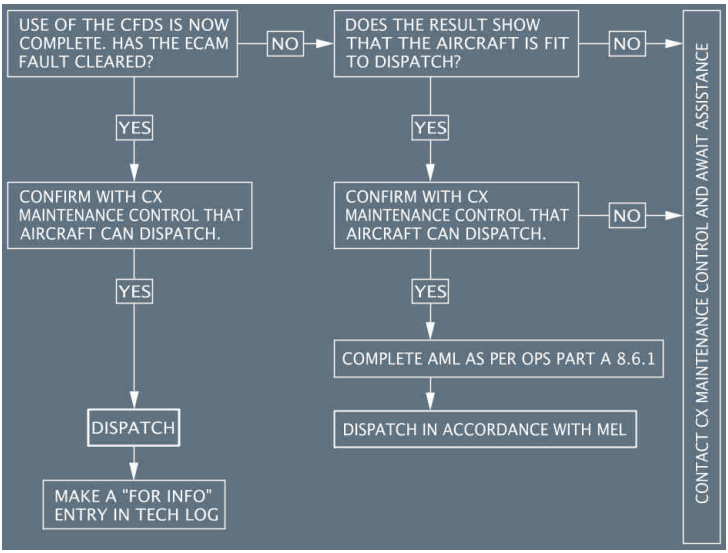
Continued from the previous page

ACTIONS	RESULTS
Select RETURN line key (LSK 6L) until the CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

13. Close circuit breaker 8CV (121 VU Q21).

Note: *Circuit breaker 7CV (121 VU R21) remains open for DISPATCH.*

14. Set the flap lever to position 0, the slats and flaps move to position 0.
15. On the panel 50 VU, release the BLUE PUMP OVRD pb-sw (ON legend extinguished).
16. On the panel 40 VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguished).
17. Check the applicable MEL limitations have been complied with then exit the procedure using the flow chart below.



6. SFCS 1 FLAP WTB SOLENOID TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL FLAP TIP BRK FAULT the following procedure checks the operation of the SFCS 1 flap Wing Tip Brake solenoids.

1. Energize the aircraft

2. Refer to MEL/MI-27-51-03A Flap Wing Tip Brakes Solenoid and check for any limitations that apply.
3. On the panel 50 VU, push the BLUE PUMP OVRD pb-sw (ON legend illuminated).
4. On the panel 40 VU, push the YELLOW ELEC PUMP pb-sw (ON legend illuminated).

Note: *Wait until the hydraulic pressure has stabilized before entering CFDS.*

5. Open following circuit breakers:

FIN	DESIGNATION	LOCATION
7CV	FLIGHT CONTROLS/SLT/CTL/SYS 2	121 VU R21
8CV	FLIGHT CONTROLS/FLP/CTL AND MONG/SYS 2	121 VU Q21

CAUTION	CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.

6. Set the flap lever to the position 3, the slats and flaps move to the position 3.
7. Do the following procedure:

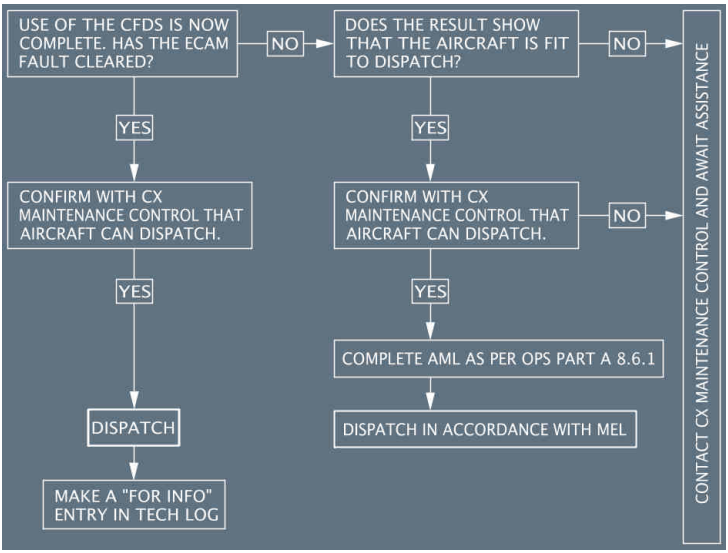
ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L)	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 1 line key (LSK 3L).	SFCC-1 page appears
Press NEXT PAGE P/B.	Second SFCC-1 page appears
Select TEST/RESET FLP line key (LSK 1R).	SFCC-1 FLAP TEST/RESET page appears.
Select WTB/ POB TEST line key (LSK 2L).	SFCC-1 FLAP WTB/POB TEST instructions page appears.
Select CONTINUE line key (LSK 5L)	Second SFCC-1 FLAP WTB/POB TEST instructions page appears. Note: *The page normally flashes off and on periodically.*
Select START TEST line key (LSK 5L).	SFCC-1 FLAP WTB/POB TEST IN PROGRESS message appears. 1. Check the following message is displayed within approximately 2 min, otherwise - NO DISPATCH: PERFORMED NO FAULTS Note: *If the test is unsuccessful after 3 attempts (˝CFDS TEST INVALID˝), try another test with a ground power cart connected or with the engine driven hydraulic pumps on and cranking the related engine 2.*

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

8. Close circuit breakers 7CV (121 VU R21) and 8CV (121 VU Q21).
9. Set the flap lever to position 0, the slats and flaps move to position 0.
10. On the panel 50VU, release the BLUE PUMP OVRD pb-sw (ON legend extinguished).
11. On the panel 40VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguished).
12. Check the applicable MEL limitations have been complied with then exit the procedure using the flow chart below.



7. SFCS 1 SLAP WTB SOLENOID TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL SLAT TIP BRK FAULT the following procedure checks the operation of the SFCS 1 slat Wing Tip Brake solenoids.

1. Energize the aircraft
2. Refer to MEL/MI-27-81-01A Slat Wing Tip Brakes Solenoid and check for any limitations that apply.

3. On the panel 50 VU, push the BLUE PUMP OVRD pb-sw (ON legend illuminated).
4. On the panel 40 VU, push the YELLOW ELEC PUMP pb-sw (ON legend illuminated).

Note: *Wait until the hydraulic pressure has stabilized before entering CFDS.*

5. Open following circuit breakers:

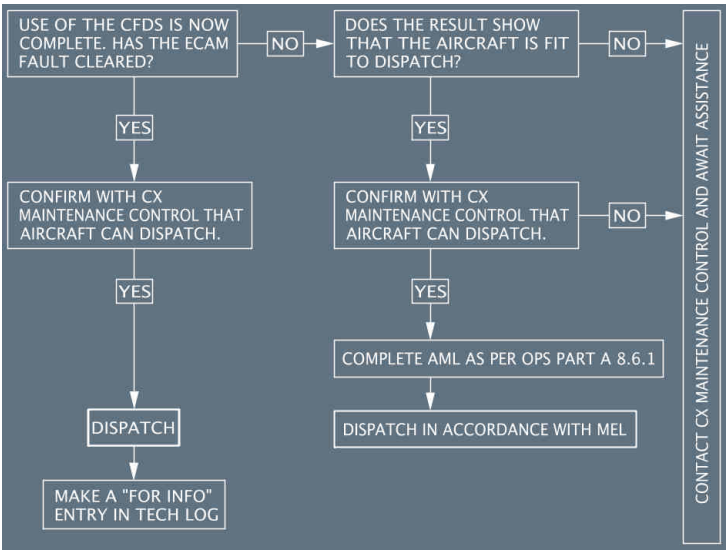
FIN	DESIGNATION	LOCATION
7CV	FLIGHT CONTROLS/SLT/CTL/SYS 2	121 VU R21
8CV	FLIGHT CONTROLS/FLP/CTL AND MONG/SYS 2	121 VU Q21

CAUTION	CHECK THE AREA AROUND THE FLAPS AND SLATS IS CLEAR OF OBSTACLES.

6. Set the flap lever to the position 3, the slats and flaps move to the position 3.
7. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key	MCDU MENU page appears.
Select CFDS line key (LSK 4L)	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select SFCC 1 line key (LSK 3L).	SFCC-1 page appears
Press NEXT PAGE P/B	Second SFCC-1 page appears
Select SLT TEST/RESET line key (LSK 1L).	SFCC-1 SLAT TEST/RESET page appears.
Select WTB/POB TEST line key (LSK 2L).	SFCC-1 SLAT WTB/POB TEST instructions page appears.
Select CONTINUE line key (LSK 5L)	Second SFCC-1 SLAT WTB/POB TEST instructions page appears. Note: *The page normally flashes off and on periodically.*
Select START TEST line key (LSK 5L).	SFCC-1 SLAT WTB/POB TEST IN PROGRESS message appears. 1. Check the following message is displayed within approximately 2 min, otherwise - NO DISPATCH: PERFORMED NO FAULTS Note: *If the test is unsuccessful after 3 attempts (˝CFDS TEST INVALID˝), try another test with a ground power cart connected or with the engine driven hydraulic pumps on and cranking the related engine 2.*
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

8. Close circuit breakers 7CV (121 VU R21) and 8CV (121 VU Q21).
9. Set the flap lever to position 0, the slats and flaps move to position 0.
10. On the panel 50 VU, release the BLUE PUMP OVRD pb-sw (ON legend extinguished)
11. On the panel 40 VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguished).
12. Check the applicable MEL limitations have been complied with then exit the procedure using the flow chart below.



8. ELEVATOR AILERON COMPUTER TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL ELAC 1 FAULT or F/CTL ELAC 1 PITCH FAULT the following procedure is used to check systems associated with ELAC 2 and the three SECs.

Note: ELAC 1 must be fully functional for ER operations, otherwise : NO DISPATCH.

1. Energize the aircraft
2. Refer to MEL/MI-27-93-01A ELAC 1 and check the items listed under paragraphs 5), 6), 7) are operative and the requirement of paragraph 8), is complied with. The items listed under paragraphs 2), 3), 4) are covered by continuing below.
3. On the panel 23 VU, release the ELAC 1 pb (OFF legend illuminated).

4. On the panel 24 VU, check the ELAC 2 pb is pushed in (OFF and FAULT legends extinguished).
5. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select EFCS 1 line key (LSK 1L).	EFCS 1 page appears.
Select GROUND SCAN line key (LSK 4L).	EFCS 1 GROUND SCAN page appears with this message displayed: - START GROUND SCAN - WAIT 2 MINUTES - STOP GROUND SCAN <START GROUND SCAN STOP> <GROUND REPORT
Select START GROUND SCAN line key (LSK 4L).	The page disappears and comes up again. Note: *The same page is displayed without any complementary information about the test progress.*
Wait for 2 min minimum.	
Select GROUND SCAN STOP line key (LSK 4R).	The page disappears and comes up again.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select GROUND REPORT line key (LSK 5L).	EFCS 1 GROUND REPORT page appears. 1. Check for the following messages: - ELAC2 MON OR WIRING FROM ACCLRM3 12CE3 - ELAC2 COM OR WIRING FROM ACCLRM3 12CE3 - ACCLRM3 12 CE3 - SEC2 OR WIRING FROM ACCLRM3 12CE3 - ELAC2 MON OR WIRING FROM ACCLRM4 12CE4 - ELAC2 COM OR WIRING FROM ACCLRM4 12CE4 - ACCLRM4 12CE4 - SEC2 OR WIRING FROM ACCLRM4 12CE4 - ELAC2 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - ELAC2 OR INPUT F/O ROLL CTL SSTU 4CE2 - ELAC2 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - ELAC2 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - SEC1 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC2 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC3 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC1 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC2 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC3 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC1 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - SEC2 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - SEC1 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - SEC2 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - CAPT ROLL CTL SSTU 4CE1 - F/O ROLL CTL SSTU 4CE2 - CAPT PITCH CTL SSTU 4CE3 - F/O PITCH CTL SSTU 4CE4 ● **If any of the above failure messages are present maintenance is required - NO DISPATCH.** *Note:* *The ″ELAC 1″ failure message is displayed because ELAC 1 is switched OFF.*
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

In addition to the above test procedure, do the following:

- If the ECAM warning was F/CTL ELAC 1 FAULT, go to step 6.
- If the ECAM warning was F/CTL ELAC 1 PITCH FAULT, go to step 9.

F/CTL ELAC 1 FAULT

6. Open following circuit breakers:

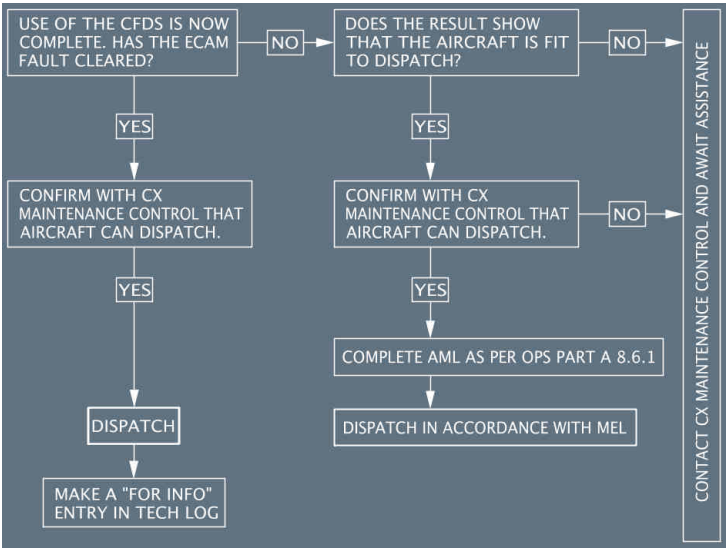
FIN	DESIGNATION	LOCATION
15 CE1	FLIGHT CONTROLS/ELAC 1/NORM/SPLY	49 VU B11
16 CE1	FLIGHT CONTROLS/ELAC 1/STBY/SPLY	105 VU AS01 (or S04)

Note: Circuit breaker panel 105 VU is located in the avionics compartment under the cockpit floor.

7. Dispatch the aircraft with circuit breakers 15 CE1 and 16 CE1 open and with ELAC 1 pb on the panel 23 VU released (OFF legend illuminated).
8. Go to step 18.

F/CTL ELAC 1 PITCH FAULT

9. On the panel 23 VU, release the SEC 1 pb (OFF legend illuminated).
10. On the panel 24 VU, release the SEC 2 pb and ELAC 2 pb (OFF legends illuminated).
11. On the panel 40 VU, push the YELLOW ELEC PUMP pb-sw (ON legend illuminated).
12. Select the FLAPS lever to position 0.
13. Move the THS with the handwheel out of the zero setting by at least one unit.
14. On the panel 24 VU, engage SEC 2. The THS must return to zero otherwise — NO DISPATCH.
15. On the panel 23 VU, engage SEC 1 (OFF legend extinguished).
16. On the panel 24 VU, engage ELAC 2 (OFF legend extinguished).
17. On the panel 40 VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguished).
18. Check the applicable MEL Operational Procedures have been completed then exit the procedure using the flow chart below.



9. SPOILER ELEVATOR COMPUTER TEST PROCEDURE

Applicable to: ALL

In the event of an ECAM warning F/CTL SEC 1(2) FAULT , the following procedure is used to check the sidestick transducers for both ELACs and the operative SECs.

Note: SEC 1 must be fully operational for ER operations, otherwise NO DISPATCH.

1. Energize the aircraft.
2. On the 23 VU panel, check ELAC 1 pb is pressed in (OFF legend extinguished).
3. On the 24VU panel, check ELAC 2 pb is pressed in (OFF legend extinguished).

- If the ECAM warning is F/CTL SEC 1 FAULT, go to step 4.
- If the ECAM warning is F/CTL SEC 2 FAULT, go to step 7.

SEC 1 FAULT

4. Refer to MEL/MI-27-94-01A SEC 1 and check that the items listed under paragraphs 3), 4), 5), 6), 7) are operative and that the requirements of paragraphs 9) and 11) are complied with. The items listed under paragraphs 8) and 10) are covered by applying the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU, press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select EFCS 1 line key (LSK 1L).	EFCS 1 page appears.
Select GROUND SCAN line key (LSK 4L).	EFCS 1 GROUND SCAN page appears with this message displayed: - START GROUND SCAN - WAIT 2 MINUTES - STOP GROUND SCAN <START GROUND SCAN STOP> <GROUND REPORT
Select START GROUND SCAN line key (LSK 4L).	The page disappears and comes up again. Note: *The same page is displayed without any complementary information about the test progress.*
Wait for a minimum of 2 min	
Select GROUND SCAN STOP line key (LSK 4R)	The page disappears and comes up again.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select GROUND REPORT line key (LSK 5L).	EFCS 1 GROUND REPORT page appears. 1. Check for the following messages: - ELAC1 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - ELAC2 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - ELAC1 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - ELAC2 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - ELAC1 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - ELAC2 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - ELAC1 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - ELAC2 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - SEC2 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC3 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC2 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC3 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC2 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - SEC2 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - CAPT ROLL CTL SSTU 4CE1 - F/O ROLL CTL SSTU 4CE2 - CAPT PITCH CTL SSTU 4CE3 - F/O PITCH CTL SSTU 4CE4 ● **If any of the above failure messages are present maintenance is required - NO DISPATCH.**
Select RETURN line (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

5. Dispatch the aircraft with the following circuit breakers open :

FIN	DESIGNATION	LOCATION
21 CE1	FLIGHT CONTROLS/SEC 1/NORM/SPLY	49 VU B08
22 CE	FLT/CTL/SEC 1/STBY/SPLY	105 VU AS01

Note: Circuit breaker panel 105 VU is located in the avionics compartment under the cockpit floor

6. Go to step 10.

SEC 2 FAULT

7. Refer to MEL/MI-27-94-02A SEC 2 and check that the items listed under paragraphs 2), 3) and 4) are operative. The items listed under paragraphs 5) and 6) are covered by applying the following procedure.

ACTIONS	RESULTS
On the LH or RH MCDU, press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select F/CTL line key (LSK 1R).	SYSTEM REPORT/TEST F/CTL page appears.
Select EFCS 1 line key (LSK 1L).	EFCS 1 page appears.
Select GROUND SCAN line key (LSK 4L).	EFCS 1 GROUND SCAN page appears with this message displayed: - START GROUND SCAN - WAIT 2 MINUTES - STOP GROUND SCAN <START GROUND SCAN STOP> <GROUND REPORT>
Select START GROUND SCAN line key (LSK 4L).	The page disappears and comes up again. Note: *The same page is displayed without any complementary information about the test progress.*
Wait for a minimum of 2 min.	
Select GROUND SCAN STOP line key (LSK 4R).	The page disappears and comes up again.

Continued on the following page

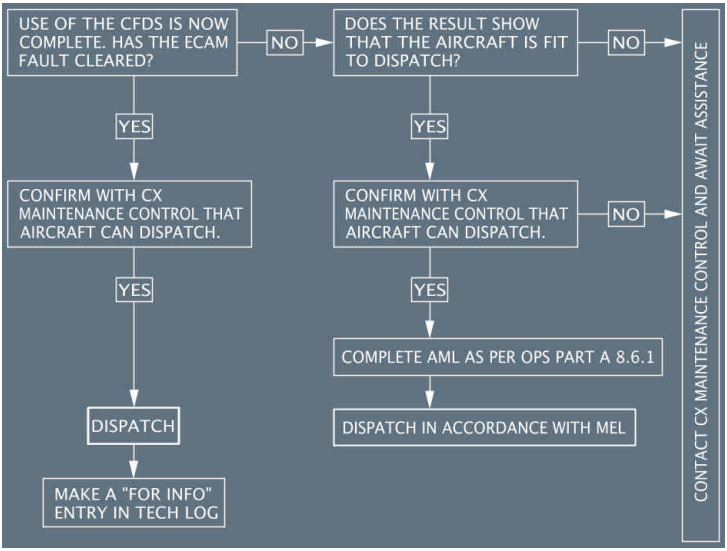
Continued from the previous page

ACTIONS	RESULTS
Select GROUND REPORT line key (LSK 5L).	EFCS 1 GROUND REPORT page appears. 1. Check for the following messages: - ELAC1 OR INPUT OFCAPT ROLL CTL SSTU 4CE1 - ELAC2 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - ELAC1 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - ELAC2 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - ELAC1 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - ELAC2 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - LACE1 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - ELAC2 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - SEC1 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC3 OR INPUT OF CAPT ROLL CTL SSTU 4CE1 - SEC1 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC3 OR INPUT OF F/O ROLL CTL SSTU 4CE2 - SEC1 OR INPUT OF CAPT PITCH CTL SSTU 4CE3 - SEC1 OR INPUT OF F/O PITCH CTL SSTU 4CE4 - CAPT ROLL CTL SSTU 4CE1 - F/O ROLL CTL SSTU 4CE2 - CAPT PITCH CTL SSTU 4CE3 - F/O PITCH CTL SSTU 4CE4 ● **If any of the above failure messages are present maintenance is required - NO DISPATCH.**
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key	MCDU MENU page appears.

8. Dispatch the aircraft with the following circuit breaker open:

FIN	DESIGNATION	LOCATION
21 CE2	FLIGHT CONTROLS/SEC 2/SPLY	121 VU Q18

9. Go to step 10.
10. Check the applicable MEL Operational Procedures have been complied with then exit the procedure using the flow chart below.



10. PROBE HEAT COMPUTER HEATING TEST

Applicable to: ALL

In the event of an ECAM warning ANTI ICE CAPT (F/O) (STBY) PROBES the first part of the following procedure is used to check the pitots are heated. (It should be noted that the Probe Heat Computers are designed so that if they fail, they do so in the on position). The second part of the procedure is used to check the operation of the Probe Heat Computers.

1. Energize the aircraft.
2. Check the following circuit breakers are closed:

FIN	DESIGNATION	LOCATION
4 DA1	ANTI ICE/PROBES/AOA/1	49 VU D04
2 DA1	ANTI ICE/PROBES/PHC/1	49 VU D03
3 DA1	ANTI ICE/PROBES/PITOT/1	49 VU D02
3 DA3	ANTI ICE/PROBES/PHC/3	122 VU Y16
1 DA2	ANTI ICE/PROBES/2/TAT	122 VU Y15
3 DA2	ANTI ICE/PROBES/2/PITOT	122 VU Y14
4 DA2	ANTI ICE/PROBES/2/AOA	122 VU Y13
2 DA2	ANTI ICE/PROBES/2/PHC	122 VU Y12
5 DA2	ANTI ICE/PROBES/2/STATIC	122 VU Y11
3 DA3	ANTI ICE/PROBES/3/PITOT	122 VU Z16

Continued on the following page

Continued from the previous page

FIN	DESIGNATION	LOCATION
4 DA3	ANTI ICE/PROBES/3/AOA	122 VU Z15
5 DA3	ANTI ICE/PROBES/3/STATIC	122 VU Z14
5 DA1	ANTI ICE/PROBES/1/STATIC	122 VU Z13
1 DA1	ANTI ICE/PROBES/1/TAT	122 VU Z12

Note: C/B could be tripped due to shorted probe

PITOT HEATING CHECK

3. On the panel 25 VU, select the PROBE/WINDOW/HEAT/AUTO/ON pb ON (ON legend illuminated).
4. Outside the aircraft check all three pitots are heated by placing a hand close to them:

CAUTION	Do not physically touch hot probe by hand.

- If all three are heated the aircraft may be dispatched as is.
  - On the panel 25 VU, release the PROBE/WINDOW HEAT pb (on legend extinguished)
  - Go to step 12 (See step 12).
- If one pitot is unheated and the ECAM warning is ANTI ICE CAPT PROBES - NO DISPATCH
- If one pitot is unheated and the ECAM warning is ANTI ICE F/O PROBES go to step 5 (See step 5).
- If one pitot is unheated and the ECAM warning is ANTI ICE STBY PROBES go to step 9 (See step 9).

F/O PROBES HEAT INOPERATIVE

5. On the panel 25 VU, release the PROBE/WINDOW HEAT pb (ON legend extinguished)
6. Select ADIRS 1, 2, 3, to the NAV position.
7. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU MENU key	MCDU MENU page appears
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

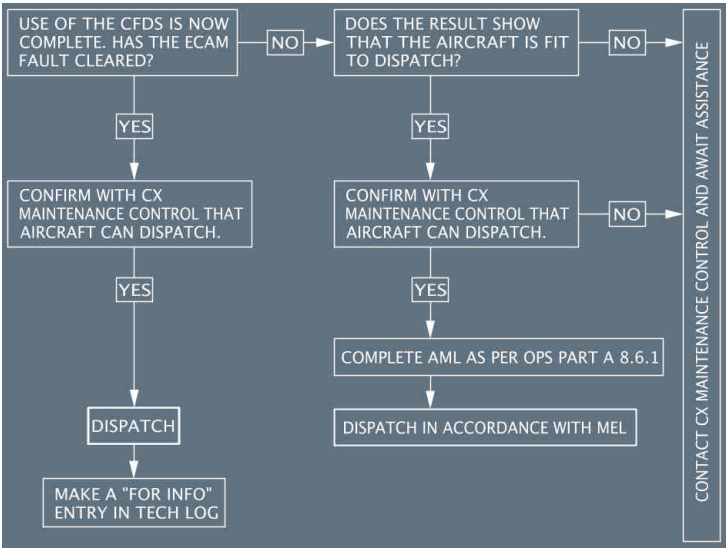
8. Go to step 12 (See step 12).

STBY PROBES HEAT INOPERATIVE

9. On the panel 25 VU, release the PROBE/WINDOW HEAT pb (ON legend extinguished)
10. Select ADIRS 1, 2, 3, to the NAV position.
11. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

12. *Refer to MEL/MI-30-31 Probe Heat Computer (PHC)* and check the applicable Operational Procedures and limitations have been complied with then exit the procedure using the flow chart below.



11. PITOT HEATER - TEST OF TWO OPERATIVE PROBE HEAT SYSTEMS

Applicable to: ALL

In the event of an ECAM warning ANTI ICE CAPT (F/O) (STBY) PITOT the following procedure is used to check the two Probe Heat Computers associated with the two operative pitots.

1. Energize the aircraft.
2. Check the following circuit breakers are closed:

FIN	DESIGNATION	LOCATION
4 DA1	ANTI ICE/PROBES/AOA/1	49 VU D04
2 DA1	ANTI ICE/PROBES/PHC/1	49 VU D03
3 DA1	ANTI ICE/PROBES/PITOT/1	49 VU D02
2 DA3	ANTI ICE/PROBES/PHC/3	122 VU Y16
1 DA2	ANTI ICE/PROBES/2/TAT	122 VU Y15
3 DA2	ANTI ICE/PROBES/2/PITOT	122 VU Y14
4 DA2	ANTI ICE/PROBES/2/AOA	122 VU Y13
2 DA2	ANTI ICE/PROBES/2/PHC	122 VU Y12
5 DA2	ANTI ICE/PROBES/2/STATIC	122 VU Y11
3 DA3	ANTI ICE/PROBES/3/PITOT	122 VU Z16
4 DA3	ANTI ICE/PROBES/3/AOA	122 VU Z15
5 DA3	ANTI ICE/PROBES/3/STATIC	122 VU Z14
5 DA1	ANTI ICE/PROBES/1/STATIC	122 VU Z13
1 DA1	ANTI ICE/PROBES/1/TAT	122 VU Z12

Note: C/B could be tripped due to shorted probe.

3. On the panel 25 VU, ensure the PROBE/WINDOW HEAT pb is released (ON legend extinguished)
4. Selected ADIRS 1, 2, 3 to the NAV position.

- If the ECAM warning is ANTI ICE CAPT PITOT go to step 5.
- If the ECAM warning is ANTI ICE F/O PITOT go to step 7.
- If the ECAM warning is ANTI ICE STBY PITOT go to step 9.

CAPTAIN'S PITOT HEAT INOPERATIVE

5. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

6. Go to step 10.

F/O PITOT HEAT INOPERATIVE

7. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

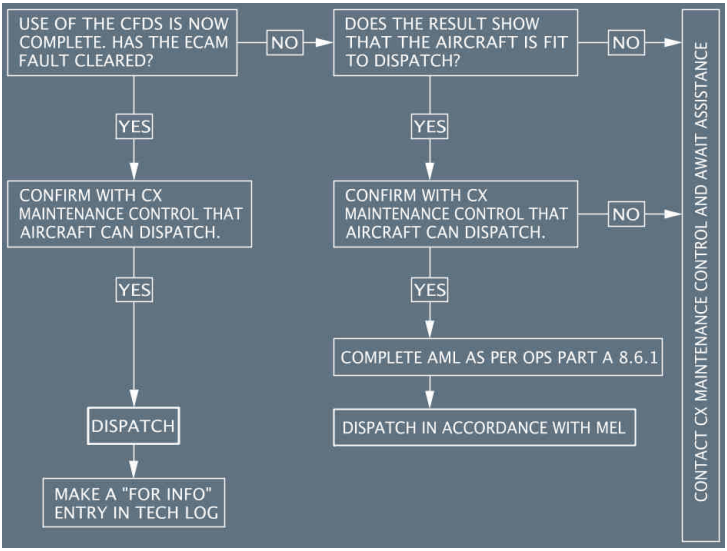
8. Go to step 10.

STBY PITOT HEAT INOPERATIVE

9. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

10. Refer to MEL/MI-30-31-02 Pitot Heater and check the applicable Operational Procedures and limitations have been complied with then exit the procedure using the flow chart below.



12. STATIC PORT HEATER - TEST OF TWO OPERATIVE PROBE HEAT SYSTEMS

Applicable to: ALL

In the event of an ECAM warning ANTI ICE CAPT L (R) STAT, ANTI ICE F/O L (R) STAT, ANTI ICE STBY L (R) STAT the following is used to check the two Probe Heat Computers associated with the operative static port heaters.

1. Energize the aircraft.
2. Check the following circuit breakers are closed :

FIN	DESIGNATION	LOCATION
4 DA1	ANTI ICE/PROBES/AOA/1	49 VU D04
2 DA1	ANTI ICE/PROBES/PHC/1	49 VU D03
3 DA1	ANTI ICE/PROBES/PITOT/1	49 VU D02
3 DA3	ANTI ICE/PROBES/PHC/3	122 VU Y16
1 DA2	ANTI ICE/PROBES/2/TAT	122 VU Y15
3 DA2	ANTI ICE/PROBES/2/PITOT	122 VU Y14
4 DA2	ANTI ICE/PROBES/2/AOA	122 VU Y13
2 DA2	ANTI ICE/PROBES/2/PHC	122 VU Y12
5 DA2	ANTI ICE/PROBES/2/STATIC	122 VU Y11
3 DA3	ANTI ICE/PROBES/3/PITOT	122 VU Z16
4 DA3	ANTI ICE/PROBES/3/AOA	122 VU Z15
5 DA3	ANTI ICE/PROBES/3/STATIC	122 VU Z14

Continued on the following page

Continued from the previous page

FIN	DESIGNATION	LOCATION
5 DA1	ANTI ICE/PROBES/1/STATIC	122 VU Z13
1 DA1	ANTI ICE/PROBES/1/TAT	122 VU Z12

3. If the ECAM warning is ANTI ICE STBY L STAT or it is ANTI ICE STBY R STAT (in other words only one of the two standby static port heaters is inoperative) then there is no need to check the Probe Heat Computers and the aircraft may be dispatched as is, go to step 11. Otherwise continue below.
4. On the panel 25 VU, ensure the PROBE/WINDOW HEAT pb is released (ON legend extinguished).
5. Select ADIRS 1, 2, 3 to the NAV position.

- If the ECAM warning is ANTI ICE CAPT L STAT and/or it is ANTI ICE CAPT R STAT (in other words one or both Captain's static port heaters inoperative) then go to step 6.
- If the ECAM warning is ANTI ICE F/O L STAT and/or it is ANTI ICE F/O R STAT (in other words one or both F/O's static port heaters inoperative) then go to step 8.
- If the ECAM warning is ANTI ICE STBY L R STAT (in other words both STBY static port heaters inoperative) then go to step 10.

CAPTAIN'S STATIC PORT HEAT INOPERATIVE

6. Do the following procedure :

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L)	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

7. Go to step 11.

F/O'S STATIC PORT HEAT INOPERATIVE

8. Do the following procedure :

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L)	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

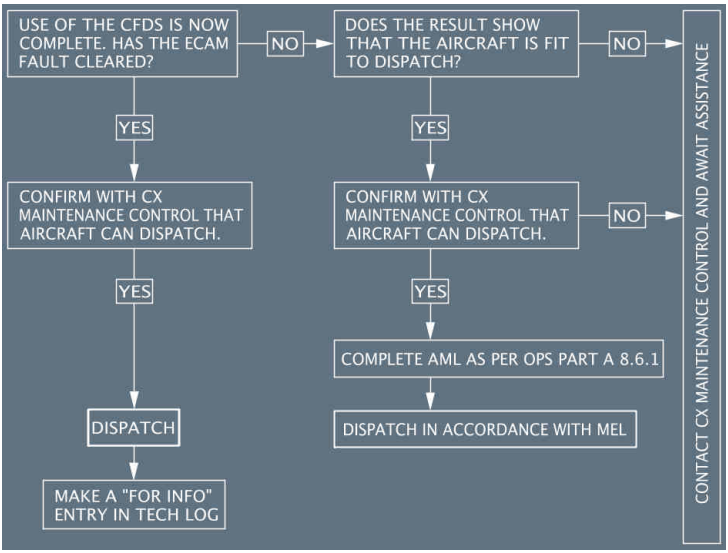
9. Go to step 11.

STBY STATIC PORT HEAT INOPERATIVE

10. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

11. Refer to MEL/MI-30-31-03 Static Ports Heater and check the applicable Operational Procedures and limitations have been complied with then exit the procedure using the flow chart below.



13. AOA PROBE HEATER - TEST OF TWO OPERATIVE PROBE HEAT SYSTEMS

Applicable to: ALL

In the event of an ECAM warning ANTI ICE CAPT (F/O) (STBY) AOA the following procedure is used to check the two Probe Heat Computers associated with the two operative AOAs.

1. Energize the aircraft
2. Check the following circuit breakers are closed:

FIN	DESIGNATION	LOCATION
4 DA1	ANTI ICE/PROBES/AOA/1	49 VU D04
2 DA1	ANTI ICE/PROBES/PHC/1	49 VU D03
3 DA1	ANTI ICE/PROBES/PITOT/1	49 VU D02
3 DA3	ANTI ICE/PROBES/PHC/3	122 VU Y16
1 DA2	ANTI ICE/PROBES/2/TAT	122 VU Y15
3 DA2	ANTI ICE/PROBES/2/PITOT	122 VU Y14
4 DA2	ANTI ICE/PROBES/2/AOA	122 VU Y13
2 DA2	ANTI ICE/PROBES/2/PHC	122 VU Y12
5 DA2	ANTI ICE/PROBES/2/STATIC	122 VU Y11

Continued on the following page

Continued from the previous page

FIN	DESIGNATION	LOCATION
3 DA3	ANTI ICE/PROBES/3/PITOT	122 VU Z16
4 DA3	ANTI ICE/PROBES/3/AOA	122 VU Z15
5 DA3	ANTI ICE/PROBES/3/STATIC	122 VU Z14
5 DA1	ANTI ICE/PROBES/1/STATIC	122 VU Z13
1 DA1	ANTI ICE/PROBES/1/TAT	122 VU Z12

Note: C/B could be tripped due to shorted probe.

3. On the panel 25 VU, ensure the PROBE/WINDOW HEAT pb is released (ON legend extinguished).
4. Select the ADIRS 1, 2, 3 to the NAV position.

- If the ECAM warning is ANTI ICE CAPT AOA go to step 5.
- If the ECAM warning is ANTI ICE F/O AOA go to step 7.
- If the ECAM warning is ANTI ICE STBY AOA go to step 9.

CAPTAIN'S AOA HEAT INOPERATIVE

5. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	"TEST WAIT" message appears first. After a few seconds "TEST OK" message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L).	"TEST WAIT" message appears first. After a few seconds "TEST OK" message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

6. Go to step 10.

F/O'S AOA HEAT INOPERATIVE

7. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 3 line key (LSK 5L).	PHC 3 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

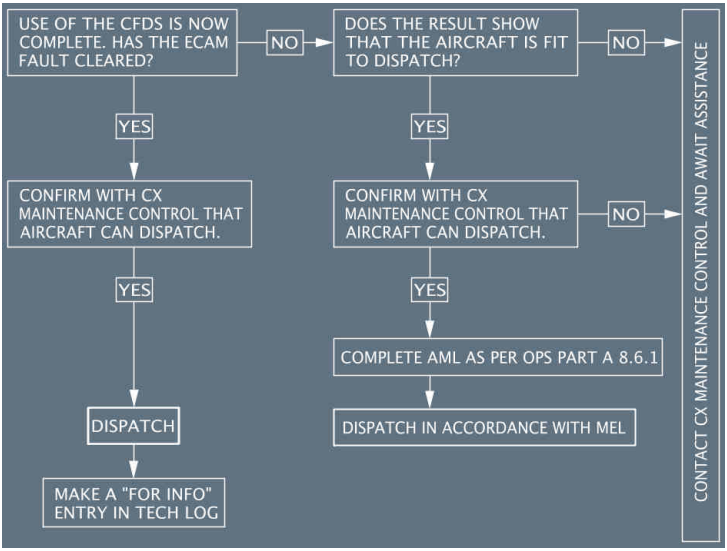
8. Go to step 10.

STBY AOA HEAT INOPERATIVE

9. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 1 line key (LSK 3L).	PHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) twice.	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select PHC 2 line key (LSK 4L).	PHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

10. Refer to MEL/MI-30-31-04 Angle of Attack (AOA) Probes Heating and check the applicable limitations have been complied with then exit the procedure using the flow chart below.



14. WINDOW HEAT COMPUTER - TEST OF THE OPERATIVE WINDOW HEAT SYSTEMS

Applicable to: ALL

In the event of a Window Heat Computer failure (ECAM warnings ANTI ICE L WINDOW and ANTI ICE L WINDSHIELD both displayed together or ECAM warnings ANTI ICE R WINDOW and ANTI ICE R WINDSHIELD both displayed together) the following procedure is used to check the remaining operative Window Heat Computer.

1. Energize the aircraft
2. Check the following circuit breakers are closed:

FIN	DESIGNATION	LOCATION
4 DG2	ANTI ICE/WINDOWS/R	122 VU W14
5 DG2	ANTI ICE/WHC/2	122 VU W13
4 DG1	ANTI ICE/WINDOW/L	122 VU X14
5 DG1	ANTI ICE/WHC/1	122 VU X13
1 DG1	ANTI ICE/L/WSHLD	123 VU AF10
1 DG2	ANTI ICE/R/WSHLD	123 VU AF03

3. On the panel 25 VU, ensure the PROBE/WINDOW HEAT pb is released (ON legend extinguished).

- If the ECAM warning is ANTI ICE L WINDOW and ANTI ICE L WINDSHIELD go to step 4 (See step 4).
- If the ECAM warning is ANTI ICE R WINDOW and ANTI ICE R WINDSHIELD go to step 6 (See step 6).

LEFT HAND SIDE WINDOW AND WINDSHIELD HEAT INOPERATIVE

4. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select WHC 2 line key (LSK 2L).	WHC 2 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

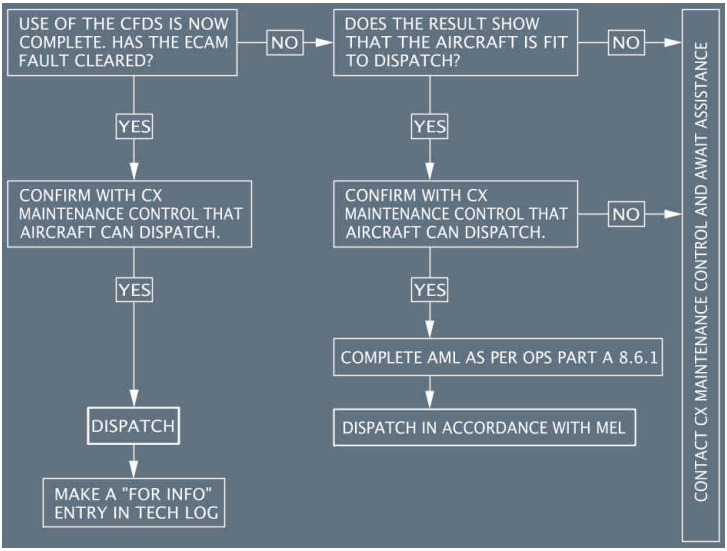
5. Go to step 7 (See step 7).

RIGHT HAND SIDE WINDOW AND WINDSHIELD HEAT INOPERATIVE

6. Do the following procedure:

ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select ICE and RAIN line key (LSK 3R).	SYSTEM REPORT/TEST ICE and RAIN page appears.
Select WHC 1 line key (LSK 1L).	WHC 1 page appears.
Select TEST line key (LSK 2L).	″TEST WAIT″ message appears first. After a few seconds ″TEST OK″ message must appear otherwise - NO DISPATCH.
Select RETURN line key (LSK 6L) until CFDS main menu appears.	CFDS main menu page appears.
Press MCDU MENU key.	MCDU MENU page appears.

7. *Refer to MEL/MI-30-42 Window Heat Computer* and check the limitations in paragraph a) are complied with then exit the procedure using the flow chart below.



15. TEST OF THE GEAR NOT DOWN ECAM WARNING

Applicable to: ALL

If the red down arrow light on the landing gear selector panel is inoperative, the following procedure is used to check the L/G GEAR NOT DOWN ECAM warning.

CAUTION	As a safety precaution, make sure that the ground safety locks are on the landing gear.

1. Energize the aircraft electrical circuits.
2. On the ECAM select the WHEEL SD page.
3. Select ON the YELLOW ELEC PUMP pb-sw

Note: PTU may be selected OFF to avoid pressurization of the green hydraulic system.

CAUTION	Check area around the flaps.

4. Select FLAP 3 or FULL.
5. Open the following C/B :

FIN	DESIGNATION	LOCATION
2 GA	HYDRAULIC/LGCIU/SYS 2	121 VU Q35
1DA1	ANTI ICE/PROBES/1/TAT	122 VU Z12

Continued on the following page

Continued from the previous page

FIN	DESIGNATION	LOCATION
1DA2	ANTI ICE/PROBES/2/TAT	122 VU Y15
3DA1	ANTI ICE/PROBES/PITOT/1	49 VU D02
3DA2	ANTI ICE/PROBES/2/PITOT	122 VU Y14
3DA3	ANTI ICE/PROBES/3/PITOT	122 VU Z16
4DA1	ANTI ICE/PROBES/AOA/1	49 VU D04
4D2A	ANTI ICE/PROBES/2/AOA	122 VU Y13
4DA3	ANTI ICE/PROBES/3/AOA	122 VU Z15
5DA1	ANTI ICE/PROBES/1/STATIC	122 VU Z13
5DA2	ANTI ICE/PROBES/2/STATIC	122 VU Y11
5DA3	ANTI ICE/PROBES/3/STATIC	122 VU Z14

6. Make sure that ENG 1 MASTER sw and ENG 2 MASTER sw are in the OFF position.
7. On the panel 50 VU, select ON the ENG 1 FADEC GND PWR pb-sw and ENG 2 FADEC GND PWR pb-sw.
8. On the center pedestal, put the thrust levers in the IDLE position.
9. Do the following test.

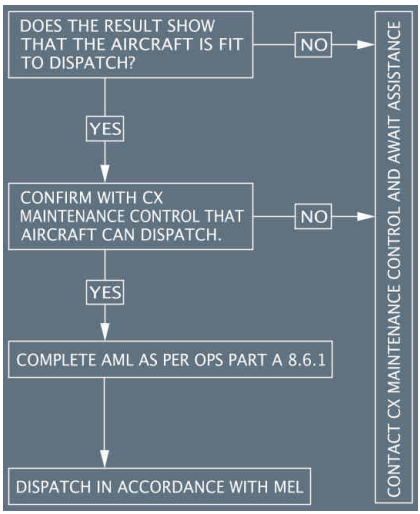
ACTIONS	RESULTS
On the LH or RH MCDU press MCDU MENU key.	MCDU MENU page appears.
Select CFDS line key (LSK 4L).	CFDS main menu page appears.
Select SYSTEM REPORT/TEST line key (LSK 5L).	SYSTEM REPORT/TEST page appears.
Select L/G line key (LSK 5R).	SYSTEM REPORT/TEST L/G page appears.
Select LGCIU 1 line key (LSK 1L)	LGCIU 1 menu page appears.
Select NEXT PAGE P/B	LGCIU 1 Page 2 menu appears
Select LANDING GEAR SIMULATION line key (LSK 1L)	LANDING GEAR SIMULATION page appears.
Select NOSE + LH + RH line key (LSK 5L)	NOSE + LH + RH page menu appears.
Select UPLOCKED line key (LSK 4L)	the UPLOCKED '<' goes off.
	On the ECAM lower DU : the WHEEL SD page shows the wheels in the UP position and L/G CTL in amber *Note:* *The amber crosses will stay on screen because the N° 2 LGCIU circuit breaker is open.* On 402 VU: the UNLK (red) indicator lights show.
	On the ECAM upper DU : the L/G GEAR NOT DOWN display comes into view and after 30 s, L/G GEAR NOT DOWNLOCKED appears.
	On the panels 130 VU and 131 VU : the MASTER WARN lights flash you can hear the warning chime.
On the ECAM CP: Depress the EMER CANC pb	The warning chime stops.
	On the panels 130 VU and 131 VU : the MASTER WARN lights go off.
	On 402VU: the UNLK (red) indicator lights stay on.

Continued on the following page

Continued from the previous page

ACTIONS	RESULTS
On the MCDU: Select DOWNLOCKED line key (LSK 3L)	On the ECAM upper DU : the L/G GEAR NOT DOWN and L/G GEAR NOT DOWNLOCKED display goes out of view. The UNLK (red) indicator lights go out and the LKD (green) indicator lights come on.
	On the ECAM lower DU: the WHEEL SD page shows the wheels in the DOWN position. *Note: The amber crosses will stay on screen because the N°2 LGCIU circuit breaker is open.*
Select RETURN line key (LSK 6L) until the CFDS menu page shows	CFDS main menu page appears.
Press the MCDU MENU line key	MCDU MENU appears.

10. Close C/B 2GA, 1DA1, 1DA2, 3DA1, 3DA2, 3DA3, 4DA1, 4DA2, 4DA3, 5DA1, 5DA2 and 5DA3
11. Set the flap lever to position 0, the slats and flaps move to position 0.
12. On the panel 40 VU, release the YELLOW ELEC PUMP pb-sw (ON legend extinguish).
13. On the panel 50 VU, release the ENG FADEC GND PWR pb-sw (ON legend extinguishes).
14. There are no applicable MEL Operational Procedures or limitations. Exit the procedure using the flow chart below.



Intentionally left blank

ATSU INITIALIZATION

Applicable to: ALL

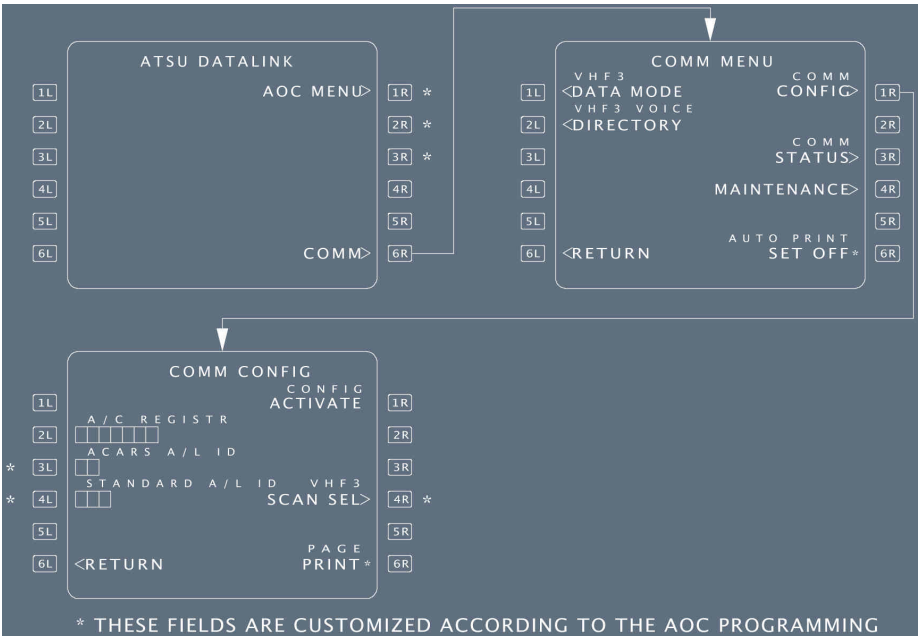
ATSU is automatically initialized, provided a list of Service Providers has been scanned, and provided the following three parameters have been received and validated by the ATSU:

- Aircraft Registration Number (ARN)
- ACARS Airline Identity code (ACARS A/L ID).
- Standard Airline Identity code (STANDARD A/L ID)

If one of the above four conditions is not fulfilled, then ATSU is not available :

- The ECAM displays ATSU FAULT,
  and
- The MCDU scratchpad displays a message to request flight crew action.

A manual entry of the missing parameter followed by its activation, reinitializes the ATSU, and clears the ECAM and MCDU message.



■ **If ARN is not valid:**

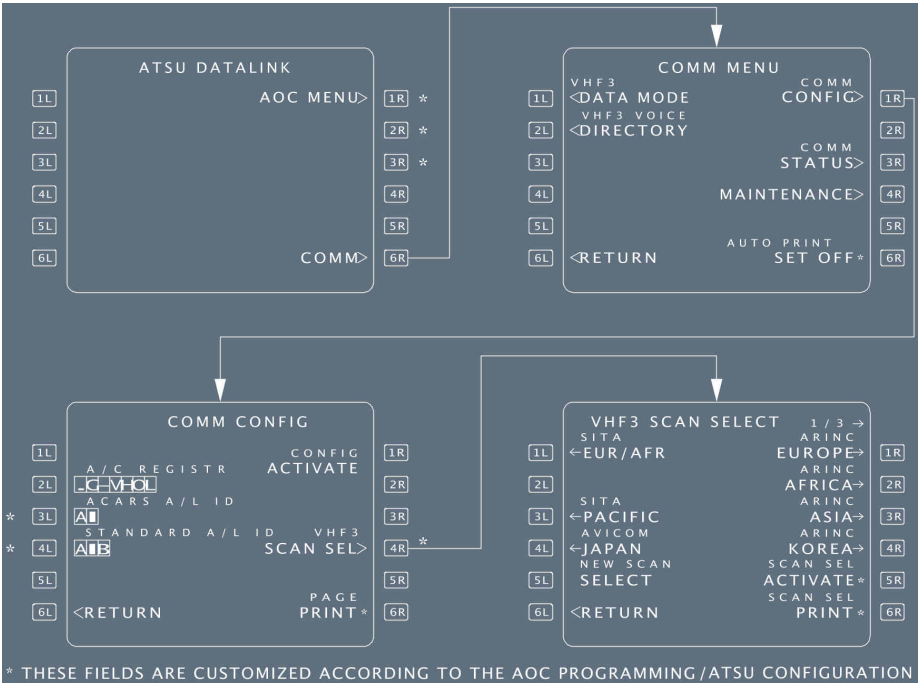
The MCDU scratchpad displays the “ENTER A/C REGISTER”message. After clearing the scratchpad, the crew writes the ARN on the scratchpad. Pressing the 2L key on the COMM

CONFIG SD page enters the ARN in the 2L field. The flight crew has to press the 1R key to activate it.

- **If the A/L ID is not valid:**
  The MCDU scratchpad displays the “ENTER A/L IDENT”message. After clearing the scratchpad, enter the two-letter A/L ID code on the scratchpad. Press the 3L key to enter the A/L ID code in the 3L field. Repeat the same operation for the three-letter A/L ID code, by using the 4L key instead of the 3L key. The flight crew has to press the 1R key to activate it.

- **If the VHF3 SCAN SELECT menu can be accessed, and if no VHF Service Providers have been selected:**
  The MCDU scratchpad displays the “ENTER VHF3 SCAN SELECT” message.
  On the VHF3 SCAN SELECT SD page, select a Service Providers' list, in the airline priority order, and activate the VHF SCAN SELECT function.

  Example : To select Service Providers SITA 725 and ARINC:
  1. Press the 5L key: The star next to SELECT indication disappears, then reappears.
  2. Press the 1L key to select SITA 725: The SELECT indication goes off, and the priority number of selection # 1 appears.
  3. Press the 1R key to select ARINC: The SELECT indication goes off, and the priority number of selection # 2 appears.
  4. Press the 5R key to activate the VHF SCAN SELECT function: The star next to the SCAN SELECT ACTIVATE indication disappears, then reappears.



Note: *Modification of the SCAN SELECT setting may result in the loss of air-ground VHF datalink communication and also in the increase of Datalink Service Providers charges. Therefore, the SCAN SELECT setting should not be modified by the flight crew, unless they have been instructed to do so.*

Intentionally left blank

THRUST CONTROL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

GENERAL

The flight crew uses console-mounted levers to control engine thrust. Each lever sends electrical signals to the FADEC of the engine it controls. The FADEC responds to the thrust lever position or an autothrust command by setting the engine thrust.

The thrust lever quadrant is the equivalent of a thrust rating panel. For each lever it has five detents. Moving the thrust lever to the forward stop of the quadrant always gives maximum takeoff or go-around thrust, as appropriate, and signals the AP/FD to go to takeoff or go-around, as appropriate. The FMA (Flight Mode Annunciator) in the left window of each PFD displays the status of the thrust system to the pilot.

The engine instrument display gives a read-out of the engine thrust mode (CL, MCT, etc.) and the appropriate engine limit. It displays the actual limit set, thrust lever position, FADEC command, and maximum engine rating limit continually.

MANUAL THRUST CONTROL

With A/THR disconnected, thrust control between full reverse (on the ground only) and maximum takeoff or go-around thrust is entirely conventional.

TLA (Thrust Lever Angle) determines the thrust demanded.

The rating limit selected by the pilot and the actual engine limit appear on the engine instrument display.

With the thrust lever short of the CL position on the quadrant, the engine instrument display shows CL continually. If one or both thrust levers are above CL, it shows MCT/FLEX. If one or both thrust levers are beyond the MCT detent, it shows TOGA. With the thrust levers positioned in a detent, the detent setting controls the engines to that limiting parameter.

AUTOTHRUST

When active A/THR controls either speed, thrust or retard as appropriate. The engine limit corresponds to the thrust lever position. If the thrust lever is below the CL detent then the TLA determines the engine power limit.

With the thrust lever above the CL detent, autothrust reverts to arm (A/THR blue on FMA) except if alpha-floor is active. CLB (or LVR CLB) flashes on the FMA.

If the thrust levers are not aligned, an asymmetric message (ASYM or LVR ASYM) appears on the FMA. If so, each engine is limited to its appropriate TLA.

This allows the use of autothrust to continue if one engine has to have its maximum RPM limited for some operational reasons such as excessive vibration.

AUTOTHRUST DISCONNECTION

Autothrust disconnection occurs when:
- The A/THR fails, or
- The FCU's A/THR pb is pressed, or
- The thrust lever(s)' instinctive disconnect button is pressed, or
- Both thrust levers are set to IDLE.
- When the radio altitude is below 100 ft and:
  - Both thrust levers above CL detent or
  - One thrust lever above MCT detent.

1. Disconnection, due to a failure or to the use of the FCU A/THR pb.
   If the thrust levers are in the CL detent (both engines operating), or one thrust lever in the MCT (one engine operative), the thrust is locked at its actual value. The FMA displays "THR LK". A single chime sounds, and an amber ECAM caution appears, as long as thrust is locked. (For more details: *Refer to Autothrust section*).
   Movement of the thrust lever(s) unlocks the thrust, and the engine then responds to TLA at the normal rate.
2. Disconnection, due to the use of instinctive disconnect button.
   When a pilot presses the instinctive disconnect button, the engines immediately develop thrust corresponding to the position of their thrust levers, whatever that might be.

INSTINCTIVE DISCONNECTION PROCEDURE

To avoid any confusion for those pilots flying the A318/A319/A320/A321 with different modifications (with, and without, energy management), Airbus recommends that pilots use one procedure for disconnecting with the instinctive disconnect button.
- Set the thrust levers to the current thrust setting by adjusting the levers until the N1 (or EPR) TLA white (blue with EIS2 screens) circle is adjacent to the N1 (or EPR) needle.
- Use the instinctive button to disconnect the A/THR.
- Check that "A/THR"memo is displayed on the ECAM, and that the autothrust mode on the first column of the FMA disappears.
- Set the thrust manually.

USE OF AUTOTHRUST IN APPROACH

The pilot should use autothrust for approaches. On final approach, it usually gives more accurate speed control, although in turbulent conditions the actual airspeed may vary from the target speed, by as much as five knots. Although the changeover between auto and manual thrust is easy to make with a little practice, the pilot should, when using autothrust for the final approach, keep it engaged until he retards the thrust levers to idle for touchdown. If the pilot is

going to make the landing using manual thrust, he should disconnect the A/THR by the time he has reached 1 000 ft on the final approach.
If he makes a shallow flare, with A/THR engaged, it will increase thrust to maintain the approach speed until he pulls the thrust levers back to idle. Therefore he should avoid making a shallow flare, or should retard the thrust levers as soon as it is no longer necessary to carry thrust, and if necessary before he receives the “retard” reminder.
Although use of the autothrust is recommended for the entire approach, this does not absolve the pilot from his responsibility to monitor its performance, and to disconnect it if it fails to maintain speed at the selected value. Such monitoring should include checking on whether or not the managed speed, calculated by the FMGC, is reasonable.
For more information concerning aircraft handling during final approach, refer to the FCOM Bulletin ”Aircraft handling in final approach”.

ENGINE FAILURE

The pilot can continue to use autothrust after an engine failure, but some pilots feel that directional control is more difficult, when autothrust changes the thrust instead of the pilot making the thrust changes manually. The choice between using, or not using, autothrust after engine failure is a personal one. As far as speed control is concerned, autothrust is usually more accurate than a pilot.

THRUST CONTROL

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

GENERAL

The flight crew uses console-mounted levers to control engine thrust. Each lever sends electrical signals to the FADEC of the engine it controls. The FADEC responds to the thrust lever position or an autothrust command by setting the engine thrust.
The thrust lever quadrant is the equivalent of a thrust rating panel. For each lever it has five detents. Moving the thrust lever to the forward stop of the quadrant always gives maximum takeoff or go-around thrust, as appropriate, and signals the AP/FD to go to takeoff or go-around, as appropriate. The FMA (Flight Mode Annunciator) in the left window of each PFD displays the status of the thrust system to the pilot.
The engine instrument display gives a read-out of the engine thrust mode (CL, MCT, etc.) and the appropriate engine limit. It displays the actual limit set, thrust lever position, FADEC command, and maximum engine rating limit continually.

MANUAL THRUST CONTROL

With A/THR disconnected, thrust control between full reverse (on the ground only) and maximum takeoff or go-around thrust is entirely conventional.
TLA (Thrust Lever Angle) determines the thrust demanded.

The rating limit selected by the pilot and the actual engine limit appear on the engine instrument display.
With the thrust lever short of the CL position on the quadrant, the engine instrument display shows CL continually. If one or both thrust levers are above CL, it shows MCT/FLEX. If one or both thrust levers are beyond the MCT detent, it shows TOGA. With the thrust levers positioned in a detent, the detent setting controls the engines to that limiting parameter.

AUTOTHRUST

When active A/THR controls either speed, thrust or retard as appropriate. The engine limit corresponds to the thrust lever position. If the thrust lever is below the CL detent then the TLA determines the engine power limit.
With the thrust lever above the CL detent, autothrust reverts to arm (A/THR blue on FMA) except if alpha-floor is active. CLB (or LVR CLB) flashes on the FMA.
If the thrust levers are not aligned, an asymmetric message (ASYM or LVR ASYM) appears on the FMA. If so, each engine is limited to its appropriate TLA.
This allows the use of autothrust to continue if one engine has to have its maximum RPM limited for some operational reasons such as excessive vibration.

AUTOTHRUST DISCONNECTION

Autothrust disconnection occurs when :
- The A/THR fails, or
- The FCU's A/THR pb is pressed, or
- The thrust lever(s)' instinctive disconnect button is pressed, or
- Both thrust levers are set to IDLE.

1. Disconnection, due to a failure or to the use of the FCU A/THR pb. If the thrust levers are in the CL detent (both engines operative), or one thrust lever in the MCT detent (one engine operative), the thrust is locked at its actual value. The FMA displays a "THR LK" pulsing memo. A single chime sounds, and an amber ECAM caution appears, as long as thrust is locked. (For more details: *Refer to Autothrust section*). Movement of the thrust lever(s) unlocks the thrust, and the engine(s) then respond(s) to TLA position.
2. Disconnection,due to the use of instinctive disconnect button.
   When a pilot presses the instinctive disconnect button, the engines immediately develop thrust corresponding to the position of their thrust levers, whatever that might be.

INSTINCTIVE DISCONNECTION PROCEDURE

To avoid any confusion for those pilots flying the A318/A319/A320/A321 with different modifications (with, and without, energy management), Airbus recommends that pilots use one procedure for disconnecting with the instinctive disconnect button.

- Set the thrust levers to the current thrust setting by adjusting the levers until the N1 (or EPR) TLA white (blue with EIS2 screens) circle is adjacent to the N1 (or EPR) needle.
- Use the instinctive button to disconnect the A/THR.
- Check that “A/THR”memo is displayed on the ECAM, and that the autothrust mode on the first column of the FMA disappears.
- Set the thrust manually.

USE OF AUTOTHRUST IN APPROACH

The pilot should use autothrust for approaches. On final approach, it usually gives more accurate speed control, although in turbulent conditions the actual airspeed may vary from the target speed, by as much as five knots. Although the changeover between auto and manual thrust is easy to make with a little practice, the pilot should, when using autothrust for the final approach, keep it engaged until he retards the thrust levers to idle for touchdown. If the pilot is going to make the landing using manual thrust, he should disconnect the A/THR by the time he has reached 1 000 ft on the final approach.

If he makes a shallow flare, with A/THR engaged, it will increase thrust to maintain the approach speed until he pulls the thrust levers back to idle. Therefore he should avoid making a shallow flare, or should retard the thrust levers as soon as it is no longer necessary to carry thrust, and if necessary before he receives the “retard” reminder.

Although use of the autothrust is recommended for the entire approach, this does not absolve the pilot from his responsibility to monitor its performance, and to disconnect it if it fails to maintain speed at the selected value. Such monitoring should include checking on whether or not the managed speed, calculated by the FMGC, is reasonable.

For more information concerning aircraft handling during final approach, refer to the FCOM Bulletin ”Aircraft handling in final approach”.

ENGINE FAILURE

The pilot can continue to use autothrust after an engine failure, but some pilots feel that directional control is more difficult, when autothrust changes the thrust instead of the pilot making the thrust changes manually. The choice between using, or not using, autothrust after engine failure is a personal one. As far as speed control is concerned, autothrust is usually more accurate than a pilot.

MANUAL ENGINE START

Applicable to: ALL

Pilots normally use automatic starting to start an engine.

However, manual starting is recommended in the following cases :

- **After aborting a start, because of :**
  - Engine stall, or Engine EGT overlimit, or LO START AIR PRESS, or No N1 rotation, or Hung start.
- **When expecting a start abort, because of :**
  - Degraded bleed performance, due to hot conditions, or at a high-altitude airfields.
  - An engine with a reduced EGT margin, in hot conditions, or at a high-altitude airfields.
  - Marginal performance of the external pneumatic power group.
  - Tailwind greater than 10 kt
    Starting in tailwind may fail due to N1 counterrotation, hot gas black flow. Fuel should be set to ON at N2 max motoring speed, provided N1 has stopped, and turn clockwise. (confirmation by the ground crew).

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

MANUAL ENGINE START PROCEDURE

CAUTION	FADEC passively monitors the start parameters. Crew shall take appropriate action in case of abnormal start.

Note: Manual starts shall be accomplished by the Captain.

THR LEVERS.....IDLE

CAUTION	The engine will start, regardless of the thrust lever position, and will rapidly accelerate to generate the thrust demanded by the TLA, causing a hazardous situation, if the thrust levers are not at idle.

ENG MODE selector.....NORM THEN IGN

The lower ECAM displays the engine page.

ENG MAN START pb .....ON

- *Do not set the MAN START pb to ON, before all amber crosses except on N1 and N2, have disappeared on engine parameters (upper ECAM display).*
- *The N1 and N2 indications show amber crosses, until the actual N1 and N2 reach about 4 % .*
- *On the ECAM lower display, check that the START VALVE is inline*
- *On the ECAM displays, check that the OIL PRESS increases, and N2 increases.*

- **If N2 does not reach 15 % , check that the pack valves have correctly closed.**

  During engine start, if the APU bleed is used and pack valves are closed, shed APU electrical loads to increase bleed air pressure, as follows:

  GALLEY.....OFF

  - **If needed, shed also :**
    BLUE ELEC PUMP (ground only).....OFF
    FUEL X FEED.....ON
    FUEL PUMPS except R TK PUMP 2.....OFF
    BLOWER..... OVRD
    CAB FANS.....OFF

  - **If additional shedding is required,** engine pump may be switched OFF (it should be ON for second engine start for PTU auto test).

- **When N2 reaches the maximum motoring speed (minimum 15 %) and 30 s after selection of the MAN START pushbutton :**

  Maximum motoring speed is reached when a significant decrease in N2 acceleration is observed. Do not attempt start unless N2 is at least 15 %

  MASTER switch..... ON

  The F/O starts the timing for monitoring the light-up delay.

  ECAM displays.....CHECK

  Check :
  - *Indication of igniters A and B*
  - *Fuel flow increase (with current EEC std, FF indication spiking occurs at fuel on)*
  - *EGT increase 20 s (maximum) after fuel is on.*
  - *N1 increases before 34 % N2*

  If the electrical power supply is interrupted during the start sequence (indicated by loss of ECAM CRTs), abort the start by setting the MASTER switch to OFF. Then perform a 30 s dry crank.

- **When N2 reaches 43 %**

  ECAM displays.....CHECK

  Check :
  - *Igniter indication off (at 43 % N2)*
  - *START VALVE crossline (N2 slightly above 43 %)*
  - *Main and secondary engine idle parameters normal.*

  Gray background on N2 indication disappears.

  MAN START.....OFF
  ENG MODE selector.....NORM

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

MANUAL ENGINE START PROCEDURE

CAUTION	FADEC passively monitors the start parameters. Crew shall take appropriate action in case of abnormal start.

Note: *Manual starts shall be accomplished by the Captain.*

THR LEVERS.....IDLE

CAUTION	The engine will start, regardless of the thrust lever position, and will rapidly accelerate to generate the thrust demanded by the TLA, causing a hazardous situation, if the thrust levers are not at idle.

ENG MODE selector.....NORM THEN IGN

The lower ECAM displays the engine page.

ENG MAN START pb .....ON

- *Do not set the MAN START pb to ON, before all amber crosses except on N1 and N2, have disappeared on engine parameters (upper ECAM display).*
- *The N1 and N2 indications show amber crosses, until the actual N1 and N2 reach about 4 % .*
- *On the ECAM lower display, check that the START VALVE is inline*
- *On the ECAM displays, check that the OIL PRESS increases, and N2 increases.*

● **If N2 does not reach 15 % , check that the pack valves have correctly closed.**

During engine start, if theAPU bleed is used and pack valves are closed, shed APU electrical loads to increase bleed air pressure, as follows:

GALY &CAB .....OFF

● **If needed, shed also :**
BLUE ELEC PUMP (ground only).....OFF
FUEL X FEED.....ON
FUEL PUMPS except R TK PUMP 2.....OFF
BLOWER..... OVRD
CAB FANS.....OFF

● **If additional shedding is required,** engine pump may be switched OFF (it should be ON for second engine start for PTU auto test).

● **When N2 reaches the maximum motoring speed (minimum 15 %) and 30 s after selection of the MAN START pushbutton :**

Maximum motoring speed is reached when a significant decrease in N2 acceleration is observed. Do not attempt start unless N2 is at least 15 %

MASTER switch.....ON

The F/O starts the timing for monitoring the light-up delay.

ECAM displays.....CHECK

Check :
- *Indication of igniters A and B*
- *Fuel flow increase (with current EEC std, FF indication spiking occurs at fuel on)*
- *EGT increase 20 s (maximum) after fuel is on.*
- *N1 increases before 34 % N2*

If the electrical power supply is interrupted during the start sequence (indicated by loss of ECAM CRTs), abort the start by setting the MASTER switch to OFF. Then perform a 30 s dry crank.

- **When N2 reaches 43 %**

ECAM displays.....CHECK

Check :
- *Igniter indication off (at 43 % N2)*
- *START VALVE crossline (N2 slightly above 43 %)*
- *Main and secondary engine idle parameters normal.*

Gray background on N2 indication disappears.

MAN START.....OFF
ENG MODE selector.....NORM

ENGINE START WITH EXTERNAL PNEUMATIC POWER

Applicable to: ALL

- **Before connecting external pneumatic power :**

PACKS 1 and 2.....OFF

(To prevent pack contamination).

- **Before start :**

APU BLEED.....OFF
ENG BLEED (both engines).....OFF
X BLEED.....OPEN

- **Cleared to start :**

Start Engine 2 first.

Note: As necessary, Engine 1 can also be started by using the external pneumatic power. If Engine 1 is started first, check the brake ACCU pressure prior to engine start.

Use the normal engine start procedure.

The minimum recommended starter air supply pressure is 25 PSI, when the start valve is open. Two external pneumatic power units may be used in parallel, if the pressure/flow relation is expected to be marginal.

- **After Engine 2 is started :**
  - **If external pneumatic power is used to start Engine 1 :**

    Start Engine 1

    Request the removal of external pneumatic power unit.
    X BLEED.....AUTO
    ENG BLEED (Both engines).....ON
    PACKS 1 and 2.....ON

  - **If the crossbleed engine start procedure is used for Engine 1 :**

    Request the removal of external pneumatic power unit
    PACKS 1 and 2.....ON
    ENG 2 BLEED.....ON
    CROSSBLEED ENGINE START PROC for Engine 1.....APPLY

CROSSBLEED ENGINE START

Applicable to: ALL

CAUTION	The use of engine bleed supply and external pneumatic power supply simultaneously is prohibited.

- **Before start :**

  APU BLEED..... OFF

  The BLEED valve of the running engine reopens and the cross bleed valve closes.

  ENG BLEED (running engine)..... check ON
  ENG BLEED (receiving engine).....OFF

  The bleed valve of engine to be started is closed to eliminate reverse flow leakage.

  X BLEED..... OPEN

- **Cleared to start :**

  Confirm area is clear of obstacles.

  Ensure increased power jet wake does not constitute any hazard to people or installation behind the aircraft.
  Adjust thrust of supplying engine to obtain 30 PSI at start air valve before start initiation and at least 25 PSI during start.
  Do not exceed 75 % N2 to limit jet wake.

Apply the normal engine start procedure.

- **After start :**

THRUST LEVER (supplying engine)..... IDLE
X BLEED..... AUTO
ENG BLEED (receiving engine)..... ON
PACKS.....Check ON

START VALVE MANUAL OPERATION

Applicable to: ALL

Advise ground crew to prepare for manual start valve operation.

AUDIO CONTROL PANEL.....CAB

- **When ground crew member is ready, order "START 1 or 2"**

ENG MODE SEL..... IGN
ENG MASTER..... ON
START VALVE..... ORDER "OPEN AND KEEP OPEN"

If not maintained in OPEN position by the ground crew member, the start valve closes.

- **When N2 at 43 %**

START VALVE..... ORDER "CLOSE"

Continue with normal procedure.

DETECTION OF HANDLING BLEED VALVE MALFUNCTION

Applicable to: ALL

- Should any evidence supporting the probability of malfunction of one or more handling bleed valve(s) be observed by the flight crew, a log book entry should be performed and a maintenance determination (and corrective action, as required) be conducted upon return to the main base or at the next out station capable of conducting such a maintenance determination/action.
  Handling bleed valve(s) malfunction may be evidenced on ground or in flight by:
  - Starting difficulties:
    - Hung start,
    - Sub-idle stall/roll back,
    - Start EGT exceedance.
  - Takeoff EGT being unexpectedly high (considering typical engine-to-engine variation and typical engine EGT margin),
  - Fuel flow shift in the order +3 % in typical cruise conditions and/or +6 % in typical climb/alternate/diversion conditions (cross-wing comparison).
  - Climb/Cruise EGT shift in the order of +20 °C to +50 °C, depending on flight phase (cross-wing comparison).

    Note: *EGT increase due to engine deterioration is associated with N2 decrease. EGT increase due to handling bleed malfunction is associated with N2 increase.*
  - Engine stall (surge) upon engine transient (acceleration or deceleration), in this particular case a maintenance action is due prior to the next flight.
- In case of starting difficulties (hung start or start stall) being experienced during ground or air start, proceed with a second or third start attempt in manual start.
  Proceeding with successive start attempts has proven to be effective in achieving a successful ground or air start.
- In case of detected Fuel Flow shift, and should one or more flight leg(s) be flown under this condition, consider adding extra fuel accordingly.

ON GROUND - NON ENG SHUTDOWN AFTER SETTING ENG MASTER SW TO OFF

Applicable to: ALL

The normal procedure to shut down an engine is to set the ENG MASTER sw to OFF. In the case where the engine does not shut down as expected, use the following procedure:

ECAM FUEL PAGE..... PRESS
LP FUEL VALVE POSITION (affected)..... CHECK

■ **If LP fuel valve is closed – cross line in amber**

No crew action. The engine will shut down after a time delay.

■ **If LP fuel valve is not closed**

ENG FIRE pb sw(affected)..... PRESS

Using the engine fire pushbutton will force the LP fuel valve to close. The engine will shut down after a time delay.

TIME DELAY

The affected engine will shut down when all the fuel between the LP fuel valve and the engine nozzles is burned by the engine. The shutdown of the engine can take up to 2 min and 30 s , depending on airport altitude and fuel recirculation system operation.
Keep ground staff informed.

Intentionally left blank

GENERAL

Applicable to: ALL

Except in some operational conditions, such as uphill slopes, slippery taxiways, or high gross weight, it may be advisable to taxi on one engine. The flight crew must exercise caution when taxiing on one engine to avoid generating excessive jet blast.

DEPARTURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

One engine taxi for departure should only be considered in exceptional circumstances, such as extended ATC delays, to prevent fuel on board reducing below the minimum sector requirement.

BRAKE ACCU PRESS.....CHECK

If necessary, use the Y ELEC PUMP to pressurize the brake accumulator.

ENGINE 1..... START

After a shutdown period of more than two hours, to avoid thermal shock, the flight crew should operate the engine at or near idle for at least five minutes before advancing the thrust lever to high power. Taxi time may be included in the warm-up period.
Use Engine 1 for taxiing because it pressurizes the green hydraulic system (nosewheel steering + normal braking), without using the PTU.

X BLEED.....OPEN

This supplies both packs from Engine 1.

Apply the normal “AFTER START” procedures, but:

- Keep the APU running to avoid additional electrical transients and to allow the galley operation. APU BLEED should be switched off to avoid ingestion of engine exhaust gases in the air conditioning system.
- After both engines have been started, perform the ECAM STATUS check, and then select and set the engine anti-icing and/or wing anti-icing as required.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

One engine taxi for departure should only be considered in exceptional circumstances, such as extended ATC delays, to prevent fuel on board reducing below the minimum sector requirement.

BRAKE ACCU PRESS.....CHECK

If necessary, use the Y ELEC PUMP to pressurize the brake accumulator.

ENGINE 1..... START

After a shutdown period of more than two hours, to avoid thermal shock, the flight crew should operate the engine at or near idle for at least five minutes before advancing the thrust lever to high power. Taxi time may be included in the warm-up period.
Use Engine 1 for taxiing because it pressurizes the green hydraulic system (normal braking).

X BLEED.....OPEN

This supplies both packs from Engine 1.

Apply the normal "AFTER START" procedures, but:
- Keep the APU running to avoid additional electrical transients and to allow the galley operation. APU BLEED should be switched off to avoid ingestion of engine exhaust gases in the air conditioning system.
- After both engines have been started, perform the ECAM STATUS check, and then select and set the engine anti-icing and/or wing anti-icing as required.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Y ELEC PUMP..... ON

This pressurizes the yellow hydraulic system.

Apply the normal "TAXI" procedures, but:
- Perform the Flight Controls checks after both engines have been started.
- Do not arm the Auto Brake system before the Flight Controls checks have been completed.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

Y ELEC PUMP..... ON

This pressurizes the yellow hydraulic system (nosewheel steering) without using the PTU.

Apply the normal "TAXI" procedures, but:
- Perform the Flight Controls checks after both engines have been started.
- Do not arm the Auto Brake system before the Flight Controls checks have been completed.

Applicable to: ALL

Y ELEC PUMP..... OFF

Correct operation of the PTU will be checked during Engine 2 start.

APU BLEED..... ON

Applicable to: ALL

- **No less than 5 min before takeoff if the engine has been shutdown for more than 2 h, and no less than 3 min before takeoff in any case:**

The last engine must be started:
- No less than 5 min before takeoff if the engine has been shutdown for 2 h or more, to avoid engine thermal shock
- No less than 3 min before takeoff in any case:
  - To avoid engine thermal shock
  - To ensure that takeoff is not initiated before the center tank pumps test is finished, since takeoff on center tank is prohibited.

ENGINE 2.....START

Note: *During engine start, a slight jerk forward may occur, if brakes are applied while the aircraft is moving.*

APU ..... AS RQRD
X BLEED..... AUTO

Continue with the "AFTER START" procedures:

After both engines have been started, perform the ECAM STATUS check, and then select and set the engine anti-icing and/or wing anti-icing as required.

Proceed with the "AFTER START" checklist.
FLIGHT CONTROLS..... CHECK
AUTO BRK .....MAX

ARRIVAL

Applicable to: ALL

The flight crew may use the following procedure to taxi in:

APU..... START

Start the APU before shutting down the engine, in order to avoid additional electrical transient.

- **No less than 3 min after high thrust operations, and when taxiing in a straight line:**

ENG 2..... SHUT DOWN

Note: *During engine shutdown, a slight jerk forward may occur, if brakes are applied while the aircraft is moving.*

Y ELEC PUMP.....ON

This avoids running the PTU.

Y ELEC PUMP..... OFF
ENG 1.....SHUT DOWN

GENERAL

Applicable to: ALL

Whenever possible, avoid areas with known or forecasted severe turbulence. If turbulence is unavoidable, aim to keep the speed in the region of the target speed given in this section, so as to provide the best protection against the effect of gust on the structural limits, whilst maintaining an adequate margin above VLS.
Sufficient buffet margin exists at optimum altitude. In order to further increase the margin to buffet onset, consider descending to a lower altitude.
Severe turbulence is defined as turbulence that causes large, abrupt changes in altitude and/or attitude. It usually causes large variations in airspeed. Occupants are forced violently against their seat belts and loose objects will move around the aircraft.
If severe turbulence occurs during a flight, the flight crew must make a logbook entry in order to initiate maintenance action.

Note: *Recommendations for severe turbulence are also applicable to extreme turbulence.*

SIGNS

Applicable to: ALL

Before entering an area of known turbulence, the flight crew and the cabin crew must secure all loose equipment and switch the cabin SIGNS to ON.
Refer to Part A 8.3.1.8 and 8.3.13.2 for policy regarding in-fight turbulence and the use of seat belts.

AUTOPILOT/AUTOTHRUST

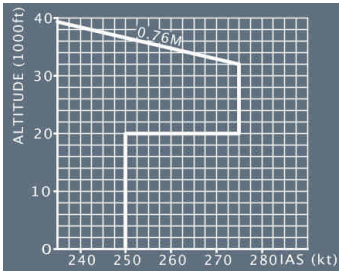
Applicable to: ALL

Keep the autopilot ON.
When thrust changes become excessive : Disconnect Autothrust.
For approach : Use A/THR for managed speed.

THRUST AND AIRSPEED

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Set the thrust to give the recommended speed (*Refer to PRO-SUP-91-10 Thrust Setting (N1) for Recommended Speed*). This thrust setting attempts to obtain, in stabilized conditions, the speed for turbulence penetration given in the graph below.
Only change thrust in case of an extreme variation in airspeed, and do not chase your Mach or airspeed.
A transient increase is preferable to a loss of speed, that decreases buffet margins and is difficult to recover.



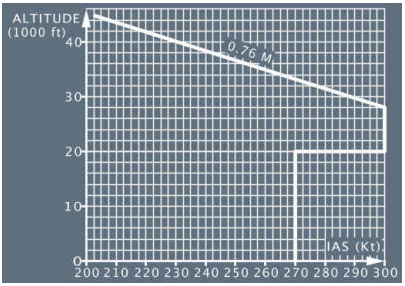
THRUST AND AIRSPEED

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Set the thrust to give the recommended speed (*Refer to PRO-SUP-91-10 Thrust Setting (N1) for Recommended Speed*). This thrust setting attempts to obtain, in stabilized conditions, the speed for turbulence penetration given in the graph below.

Only change thrust in case of an extreme variation in airspeed, and do not chase your Mach or airspeed.

A transient increase is preferable to a loss of speed, that decreases buffet margins and is difficult to recover.



THRUST SETTING (N1) FOR RECOMMENDED SPEED

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

SPEED AND THRUST SETTING FOR RECOMMENDED TURBULENCE SPEED

ALTITUDE

Applicable to: ALL

If the crew flies the aircraft manually :

- Expect large variations in altitude, but do not chase altitude.
- Maintain attitude and allow altitude to vary.

LANDING

Applicable to: ALL

Configuration FULL, or 3, can be used.
However, Configuration 3 provides more energy and less drag.

PRECAUTIONS FOR SUSPECTED WINDSHEAR

Applicable to: ALL

BEFORE TAKEOFF

Delay takeoff until conditions improve.

Evaluate takeoff conditions :
- Using observations and experience.
- Checking weather conditions.

Select the most favorable runway (considering location of the likely windshear).
Use the weather radar or the predictive windshear system ◁ before commencing takeoff to ensure that the flight path clears any potential problem areas.
Select TOGA thrust.
Monitor closely airspeed and airspeed trend during the takeoff run for early signs of windshear.

DURING APPROACH

Delay landing or divert to another airport until conditions are more favorable.

Evaluate condition for a safe landing by :
- Using observations and experience.
- Checking weather conditions.

Use the weather radar.
Select the most favorable runway, considering also which has the most appropriate approach aid.
Consider FLAPS 3.
Use managed speed in the approach phase.
Check both FDs engaged in ILS, FPA or V/S.
Engage the autopilot, for a more accurate approach and earlier recognition of deviation from the beam, when ILS is available.

Note: - *When it is using the GS mini-function, associated with managed speed, the system will carry extra speed in strong wind conditions.*
- *In case of strong or gusty crosswind greater than 20 kt, Refer to QRH/FPE-IFL VAPP Determination.*

RECOVERY TECHNIQUE AT TAKEOFF

Applicable to: ALL

BEFORE V1

The takeoff should only be rejected if unacceptable airspeed variations occur below the indicated V1, and the pilot decides that there is sufficient runway remaining to stop the aircraft.

AFTER V1

Set thrust levers to TOGA
Rotate normally.
Follow SRS orders.

DURING INITIAL CLIMB

Set or maintain TOGA.
If the autopilot is engaged, use it ; but, be aware that automatic disengagement may occur, if $\alpha > \alpha$ prot.
Follow SRS orders (including use of full backstick, if demanded).

Note: If FD bars are unavailable, use an initial pitch attitude up to 17.5 ° with full backstick, if necessary. If needed, to minimize the loss of height, increase this pitch attitude.

Do not change configuration (gear, flaps), until out of shear.
Closely monitor the flight path and speed.
Recover smoothly to a normal climb, when out of shear.

RECOVERY TECHNIQUE AT LANDING

Applicable to: ALL

Set thrust levers to TOGA.
If the autopilot is engaged, use it ; but, be aware that automatic disengagement may occur, if $\alpha > \alpha$ prot.
Follow SRS orders.

Note: If FD bars are unavailable, use an initial pitch attitude up to 17.5 ° with full backstick, if necessary. If needed, to minimize the loss of height, increase this pitch attitude.

Do not change configuration.
Closely monitor the flight path and speed.
Recover smoothly to a normal climb, when out of shear.

GENERAL

Applicable to: ALL

For flight operations in icing conditions, *Refer to PRO-SUP-30 Operations in Icing Conditions*.
For ground operations on contaminated runways, *Refer to PER-TOF-CTA-10 GENERAL*.
The preparation and ground operation of the aircraft, after it has been sitting idle in very low temperatures, may present particular problems. In such cases, the flight crew should use the following procedures, which complement the normal operating procedures.
Ice accumulates on the aircraft when the air temperature approaches, or falls below, freezing (0 °C) and there is precipitation or condensation. Ice may also build up when the aircraft is exposed to any form of moisture, after the surfaces have been cold-soaked during previous cruise flight at high altitudes, after the aircraft has been refueled with cold fuel, or after it has been exposed to low overnight air temperatures.

EXTERIOR INSPECTION

Applicable to: ALL

PRELIMINARY COCKPIT PREPARATION (normal procedures)..... COMPLETED

APU is started and air conditioning is on.

ICE/SNOW..... REMOVE FROM WINDSHIELD/UPPER COCKPIT FUSELAGE

CAUTION	With ice or snow accumulated on the windshield/upper cockpit fuselage, and if the PROBE/WINDOW HEAT pb is turned on, melted snow running down from the cockpit windows could re-freeze on the fuselage area below, when the temperature is very low. This could create ice build up on the forward fuselage that could possibly disturb the airflow around the static/pitot probes.

PROBE/WINDOW HEAT.....ON

Note: *Ensure that the probe covers are removed in order to prevent the probe covers from melting.*

SURFACES.....CHECKED FREE OF FROST, ICE AND SNOW

All surfaces of the aircraft (critical surfaces : leading edges and upper surfaces of wings, vertical and horizontal stabilizers, all control surfaces, slats and flaps) must be clear of snow, frost and ice for takeoff.
Thin hoarfrost is acceptable on the upper surface of the fuselage.

Note: *Thin hoarfrost is typically a white crystalline deposit which usually develops uniformly on exposed surfaces on cold and cloudless nights ; it is so thin that a person can distinguish surface features (lines or markings) beneath it.*

On the underside of the wing tank area, a maximum layer of 3 mm (1/8 in) of frost will not penalize takeoff performance.

FOLLOWING EQUIPMENT.....CHECKED FREE OF FROST, ICE AND SNOW

- *Landing gear assemblies (lever locks) and tires, landing gear doors.*
- *Engine inlets, inlet lips, fans (check for rotation), spinners, fan exhaust ducts, reverser assemblies.*
- *Drains, bleeds, probes (pitots, static ports, TAT sensors, angle of attack sensors).*
- *Fuel tank ventilation.*
- *Radome.*
- *Verify that the commercial water supplies are not frozen and have been refilled (these should have been emptied prior to the cold soak).*

● **After first engine start**

PROBE/WINDOW HEAT.....AUTO

Heating will continue to operate but under automatic control.

DEICING/ANTI-ICING PROCEDURE ON GROUND

Applicable to: ALL

GENERAL

In all situations, it is the Captain's responsibility to decide if the ground crew must deice/anti-ice the aircraft, and/or if additional deicing/anti-icing treatment is required.
Before starting the deicing/anti-icing procedure, the flight crew must establish communication with the ground crew that will be applying the procedure.

CAUTION	- Make sure that the low or high-pressure ground connectors do not supply any external air to the aircraft. - If it is necessary for the ground crew to repeatedly anti-ice the aircraft, they must deice the surfaces with a hot fluid mixture before applying a new layer of anti-icing fluid.

Make sure that the ground crew uses the correct de-icing/anti-icing fluids, in accordance with Part A 8.2.3.
The aircraft can be deiced or anti-iced when the APU and engines are either stopped or running. However, do not start the engines when the ground crew is spraying fluid on the aircraft.

CAUTION	- The ground crew should take care when spraying deicing fluid, and make sure that the engine and APU do not ingest any fluid. - Do not move flaps, slats, ailerons, spoilers, or elevators, if they are not free of ice. - Always ensure that both the left and right sides of the aircraft receive the same, complete, and symmetrical deicing/anti-icing treatment.

Note: *In the case of frost formation on one or several areas of the wing surface, the captain can request a local de-icing application only on the affected areas. The captain shall take care that both wings must receive the same symmetrical treatment even if frost formation does not affect symmetrically both wings.*

BEFORE SPRAYING FLUID

CAB PRESS MODE SEL.....CHECK AUTO
ENG BLEED 1 + 2.....OFF
APU BLEED.....OFF
DITCHING pb .....ON

Outflow valve, pack valves, and avionic ventilation inlet and extract valves close.
This prevents de-icing fluid from entering the aircraft. Avionic ventilation is in a closed circuit with both fans running. In view of the low OAT, there is no time limit for this configuration.
However, in order not to affect passengers comfort, it is recommended to avoid packs inoperative for longer than 20 min.

Note: *If the "VENT AVNCS SYS FAULT" warning appears, reset the AEVC circuit breaker at the end of the aircraft de-icing procedure.*
AIR COND/AVNCS VENT/CTL D06 on 49VU.
AIR COND/AVNCS/VENT/MONG Y17 on 122 VU.

THRUST LEVERS.....CHECK IDLE
"AIRCRAFT PREPARED FOR SPRAYING"..... INFORM GROUND CREW

UPON COMPLETION OF THE SPRAYING OPERATION

DITCHING pushbutton.....OFF
OUTFLOW VALVE.....CHECK OPEN

On the ECAM PRESS page, confirm that the outflow valve indication reaches the open green position to avoid any unexpected aircraft pressurization.

ENG BLEED 1 + 2.....ON
PITOTS and STATICS (ground crew).....CHECK

CAUTION	When the OAT is low (below -5 °C) during snow/freezing rain precipitations and with crosswind conditions, melted snow or raindrops may drip from the cockpit windshields and freeze on the fuselage below. Ice may then build up and possibly disturb the airflow around the static/pitot probes, and result in unreliable air data measurements during takeoff. Therefore during taxi out before takeoff beware of this possible build up of ice. The area around static/pitot probes must be free of ice/snow before starting takeoff.

GROUND EQUIPMENT..... REMOVE
DE-ICING/ANTI-ICING REPORT..... RECEIVED

The information from ground personnel, who performed the de-icing and post-application check, must include (ANTI-ICING CODE) :

- *Type of fluid used*
- *The mix ratio of fluid to water (for example 75/25)*
- *When the holdover time began.*
- *Result of post application check; aircraft critical parts are clean.*

● **A few minutes after completion of spraying operation :**

APU BLEED..... ON

Note: If the fuselage has been sprayed, there is a risk of de-icing fluid ingestion by the APU air intake, resulting in specific odors, or smoke warnings. Therefore:

- *Keep the APU running with the APU BLEED OFF for about 5 min after spraying completion before setting the APU BLEED to ON,*
- *Consider APU BLEED OFF for takeoff.*

NORMAL PROCEDURE..... RESUME

Apply appropriate normal procedures. Pay special attention to the flight control check. In freezing precipitation, perform the appropriate checks to evaluate aircraft icing. Base the decision on whether to takeoff, or to re-protect the aircraft, on the amount of ice that has built up on the critical surfaces since the last de-icing, as revealed by a personal inspection from the inside and outside of the aircraft. Make this inspection before the holdover time expires, or just before takeoff.

SECURING THE AIRCRAFT FOR COLD SOAK

Applicable to: ALL

● **After switching off all bleeds, and before switching off AC power :**

DITCHING pushbutton..... ON

This closes the outflow valve, the pack valves, and the avionic ventilation inlet and extract valves.

PARKING BRAKE.....OFF

Check chocks in place, and release the parking brake to prevent brakes from freezing.

- **After switching off the batteries :**

DITCHING pushbutton.....OFF
PROTECTIVE COVERS.....INSTALL

Install protective covers and plugs to protect the aircraft and engines from snow and ice.

WATER SYSTEM DRAINING

Applicable to: ALL

Drain the water system, if the OAT requires it, as shown below :

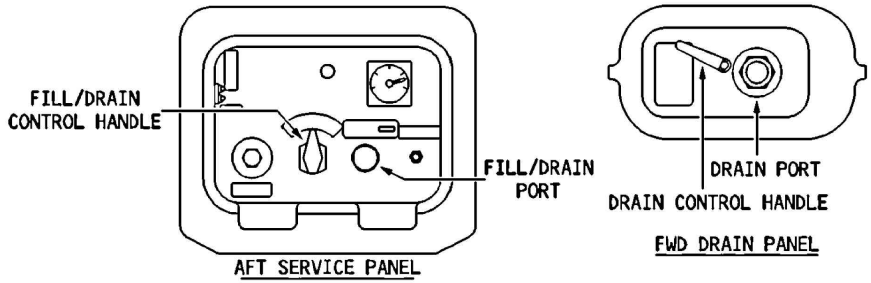
Configuration			Exposure time	Water tank drain
Air Conditioning	**Cabin temperature**	**Outside Air Temperature**		
ON	Above 10 °C (50 °F)	Between 0 °C and -15 °C (32 °F and 5 °F)	None	Not required
		Below -15 °C (5 °F)	1 h 15 min	Required
OFF		Between 0 °C and -7 °C (32 °F and 19.4 °F)	1 h 30 min	
		Between -7 °C and -15 °C (19.4 °F and 5 °F)	0 h 30 min	
		Below -15 °C (5 °F)	Any	

FOR DRAINING WATER PROCEDURE

Applicable to: ALL

INTRODUCTION

This procedure uses electrical power.



ACCESS PLATFORM(S).....PUT IN POSITION

SHUTOFF VALVE IN GALLEYS/TOILETS..... CHECK OPEN
FWD/AFT ACCESS PANEL DOORS.....OPEN
DRAIN PORT CAPS..... REMOVE

Remove drain port caps on forward drain and aft service panels.

DRAIN HOSES.....CONNECT

Connect drain hoses to :

- *the drain port on the forward drain panel.*
- *the full/drain port on the aft service panel.*

ON THE FORWARD DRAIN PANEL

DRAIN CONTROL HANDLE.....TURN LEFT

Turn the control handle to drain.

ON THE AFT SERVICE PANEL

FILL/DRAIN CONTROL HANDLE.....TURN TO “DRAIN” AND PULL

Turn the handle to the “DRAIN” position and pull it out to its mechanical stop to drain.
The indicator light comes on.

WHEN THE WATER SYSTEM IS DRAINED

In freezing conditions, the drain valves must stay open to prevent damage to the system. Do not put on the caps and leave the access door open.

DRAIN HOSES.....DISCONNECT
PANELS..... CLEAN AND DRY
ACCESS PLATFORM(S)..... REMOVE

GENERAL

Applicable to: ALL

The following procedures are recommended for operators who fly routes that could take their aircraft through the material emerging from active volcanoes.
Because volcanic ash is composed of very abrasive particles it can do serious damage to aircraft parts and impair the operation of aircraft systems significantly.
Operators should avoid airports with volcanic ash deposits if possible. If operations at such airports are unavoidable, operators should heed the following recommendations.
When operation on airport contaminated by sand or dust is expected, based on their experience and the amount of contaminant, operators can consider applying most of the on-ground recommendations in order to help preventing contamination of aircraft systems.

GROUND OPERATIONS ON AIRPORTS COVERED WITH ASH, SAND OR DUST

Applicable to: ALL

PREPARATION OF THE COCKPIT

APU .....DO NOT USE

Use the APU only to start the engines, and then only if ground power is not available, particularly in case of volcanic ash.
Request ground supply for air conditioning and for electricity.

WINDSHIELD WIPERS..... DO NOT USE

Do not use windshield wipers to remove ash, or for anything else.

BRAKE PERFORMANCE.....CONSIDER PENALTY

A layer of volcanic ash on the runway may degrade braking efficiency. Treat takeoff performance as if it is similar to that on a wet runway (dry ash) or on slush (wet ash).

EXTERIOR INSPECTION

SURFACES AND EQUIPMENT.....CHECK FREE OF DEPOSITS

Ground maintenance should remove ash, sand or dust that has settled on exposed lubricated surfaces and could penetrate seals or enter the engine gas path, air conditioning system, air data probes, access doors and panels and other orifices on the aircraft.

ENGINE/APU INLETS..... CHECK FREE OF DEPOSITS

Inspect the inlets and order them cleaned of deposit. Have the area within 25 ft of the engine inlet cleaned of volcanic ash (as much as practical).

ENGINE START

Use external pneumatic supply for starting the engines, if it is available. (*Refer to PRO-SUP-70 Engine Start with External Pneumatic Power*).

ENGINE..... CRANK

Before starting the engines, ventilate them by dry cranking at maximum motoring speed for two minutes. This will blow out any contaminant ash that may have entered the booster area.

TAXI

After releasing the brakes:

THRUST LEVERS..... ADVANCE SMOOTHLY THEN MOVE TO IDLE WHEN ROLLING

Advance the levers smoothly to the minimum required for breakaway.
Avoid making sharp or high-speed turns.

ENG 1, ENG 2 BLEED.....OFF

Keep bleed valves closed for taxiing, particularly in volcanic ash.

In case of crosswind when performing a 180 ° turn on the runway, initiate this turn with the nose down wind in order to prevent ash, sand or dust ingestion.

TAKEOFF

Allow ash, sand and dust (if present) to settle on runway before starting the takeoff roll.
Use the rolling takeoff technique if possible.
Adjust progressively engine power as for normal takeoff procedures.
To prevent contamination of air conditioning system, consider a takeoff with packs OFF.

LANDING

REVERSERS..... USE AS LIGHTLY AS FEASIBLE

If it appears that maximum reverse thrust will be needed, apply reverse thrust when the main landing gear touches down. Limit the use of reverse thrust as much as possible, because reverse flow may throw up ash, sand, dust and impair visibility.

Note: The abrasive effect of volcanic ash on windshields and landing lights may reduce the pilot's visibility for approach and landing significantly. Consider diverting to an airfield where it is possible to use AUTOLAND.

BRAKE PERFORMANCE.....CONSIDER PENALTY

A layer of volcanic ash on the runway may degrade braking efficiency. Treat landing performance as if it is similar to that on a wet runway (dry ash) or on slush (wet ash).

SECURING THE AIRCRAFT

If the aircraft is to be parked at an airport contaminated with volcanic ash, sand or dust, install engine inlet covers and other protective covers and plugs.
In addition:

- **After switching off all bleeds and before switching off AC power:**
  DITCHING pb ..... ON
  This closes the outflow valve, pack valves and avionic ventilation extract valve.

- **After switching off the batteries :**
  DITCHING pb .....OFF
  PROTECTIVE COVERS.....INSTALL
  Install protective covers/plugs, to protect the aircraft/engines from volcanic ash.

FLIGHT OPERATIONS WITH VOLCANIC ASH

Applicable to: ALL

Avoid flight into areas of known volcanic activity.
If a volcanic eruption is reported while the aircraft is in flight, reroute the flight to remain well clear of the affected area (volcanic dust may spread over several hundred miles). If possible, stay on the upwind side of the volcano (at least 20 nm upwind of it if it is erupting).

In hours of darkness or in meteorological conditions that obscure volcanic dust, one or several of the following phenomena indicate that the aircraft may be flying into ash cloud:

- smoke or dust in the cockpit,
- acrid odor similar to that of electrical smoke,
- at night, the appearance of St. Elmo's fire and static discharges around the windshield,
- bright white or orange glow appearing in the engine inlets,
- sharp, distinct beams from the landing lights,
- multiple engine malfunctions, such as rising EGT, decreasing power, stall, or flame out.

For the in-flight procedure, *Refer to VOLCANIC ASH ENCOUNTER procedure* and *Refer to QRH/ABN-80 VOLCANIC ASH ENCOUNTER*.

REPORTING

- Whenever operating in areas affected by volcanic activity, flight crews should be aware of volcanic reporting procedures and be familiar with the use of the ICAO Special Air Report of Volcanic Activity (Model VAR).
- If the aircraft encounters a volcanic ash cloud, the flight crew should report the location, altitude, and direction of drift for the ash cloud to ATC, flight conditions and crew duties permitting.

Intentionally left blank

SPRAY PATTERN

Applicable to: ALL

There is a little chance of the engines ingesting fluid, which in any case should not jeopardize safety. The risk of ingestion is independent of the depth of the contaminant.

CROSSWIND

Applicable to: ALL

To optimize directional control during the low speed phase of the takeoff and landing roll and according to the reported braking action given by the control tower, it is not recommended to take off or to land with a crosswind component higher than :

Reported braking action	Reported runway friction coefficient	Maximum crosswind (kt)		Equivalent runway condition (1)
		Takeoff	Landing	
Good (on wet runway)	≥0.4	29	33	1
Good/medium	0.39 to 0.36	29	29	1
Medium	0.35 to 0.3	25		2/3
Medium/poor	0.29 to 0.26	20		2/3
Poor	≤0.25	15		3/4
Nil		5		4/5

(1) Equivalent runway condition (only valid for maximum crosswind determination)

1. *Damp or wet runway (less than 3 mm water depth)*
2. *Runway covered with slush*
3. *Runway covered with dry snow*
4. *Runway covered with standing water with risk of hydroplaning or wet snow*
5. *Icy runway or high risk of hydroplaning*

Note: The maximum crosswind values given in the above table are recommended values based on computations. They are given without gust.

TAXIING

Applicable to: ALL

FOLLOWING TAXIING PROCEDURES.....CONSIDER

- *Avoid high thrust settings.*
- *When taxiing on slippery surfaces, stay well behind preceding aircraft.*
- *Taxi at low speed. Note that antiskid does not operate at low taxi speeds.*
- *On slippery taxiways during turns with large nose wheel steering angles, noise and vibration may result from the wheels slipping sideways. Keep speed as low as possible to make a smooth turn with minimum radius. Differential power may be needed.*

● **If taxiing in icing conditions with precipitation on runways and taxiways contaminated with slush or snow :**

Before takeoff keep flaps/slats retracted until reaching the holding point on the takeoff runway to avoid contaminating the mechanism. Hold the BEFORE TO checklist at FLAP SETTING and finish it after extending flaps/slats.

When taxiing in after landing, do not retract the flaps/slats to avoid damage of the structure.

After engine shutdown make a visual inspection to determine that the flap/slat mechanism is free of contamination.

When the mechanism is clean, use the following procedure to retract the flaps/slats before the aircraft electric network is de-energized :

- *Set the YELLOW ELEC PUMP to ON*
- *Check that the BLUE ELEC PUMP is in the AUTO position*
- *Set the BLUE PUMP OVRD to ON*
- *Retract the FLAPS and monitor retraction on ECAM page.*
- *Select off the YELLOW ELEC PUMP and BLUE PUMP OVRD and resume with normal procedure.*

Note: - *On contaminated runways and taxiways, the radio altitude indications may fluctuate and auto call outs or GPWS warnings may be activated. Disregard them.*
- *During taxi on snowy runways, the radio altimeters may not compute any data and the ECAM warnings 'DUAL ENG FAILURE', 'ANTI ICE CAPT TAT FAULT', 'ANTI ICE F/O TAT FAULT', 'L/G SHOCK ABSORBER FAULT' may be triggered. Disregard these warnings.*

TAKEOFF

Applicable to: ALL

FOLLOWING TAKEOFF PROCEDURES..... CONSIDER

- *For contaminated runways, select MAX TO.*
- *Do not abort takeoff for minor deficiencies even at low speeds.*
  If you have to abort takeoff, maintain directional control with the rudder and small inputs to the nose wheel. If necessary, use differential braking to regain the center line when stopping distance permits.
- *Do not lift the nose wheel before VR in an attempt to avoid splashing slush on the aircraft, because this produces additional aerodynamic drag.*
- *Rotate, lift off and retract gear and high lift devices in the normal manner.*

LANDING

Applicable to: ALL

FOLLOWING LANDING PROCEDURES..... CONSIDER

- *Avoid landing on contaminated runways if the antiskid is not functioning. The use of autobrake LOW or MED is recommended provided that the contamination is evenly distributed.*
- *Approach at the normal speed.*
- *Make a positive touchdown after a brief flare.*
- *As soon as the aircraft has touched down, lower the nose wheel onto the runway and select maximum reverse thrust.*
  Do not hold the nose wheel off the ground.
- *If necessary, the maximum reverse thrust can be used until the aircraft is fully stopped.*
- *If the runway length is limiting, apply the brakes before lowering the nose gear onto the runway, but be prepared to apply back stick to counter the nose down pitch produced by the brakes application. (The strength of this pitching moment will depend on the brake torque attainable on the slippery runway).*
- *Maintain directional control with the rudder as long as possible, use nose wheel steering with care.*
- *When the aircraft is at taxi speed, follow the recommendations for taxiing.*

Note: *If there is snow, visibility may be reduced by snow blowing forward at low speeds if reversers are not cancelled.*

Intentionally left blank

LOW VISIBILITY OPERATIONS

Applicable to: ALL

INTRODUCTION

Refer to Part A 8.4.1 for company policy.
The Captain occupying the LHS shall be PF.
The requirements of this section are provided as a supplement to the Normal Procedures.

TAXING

Speeds in excess of 10 kt should be avoided. The PM should use the airport chart and closely monitor the position of the aircraft. Expected headings during the taxi should be confirmed by cross-checking with the PFD/ND heading.
Complete the before takeoff procedures either before taxiing or upon reaching the holding point.

LINE UP AND TAKEOFF

Select the LS pb or ROSE LS on the EFIS CTL in order to monitor the localizer on the PFD/ND and confirm that the aircraft is lined up with the centerline of the correct runway.
During the takeoff roll, the centreline lights will appear to stream, making it easier to assess the aircraft's position relative to the centreline. The yaw bar will also provide centerline guidance (up to 30 ft RA). During the rotation, the Captain should positively transfer to instruments as soon as the visual cues disappear.

DESCENT

STRATEGY

Check the ECAM STATUS page for any degraded approach capability. Check any system fault against the table in QRH OPS.04 that lists the equipment required for the various landing capabilities.
Irrespective of the actual weather conditions, the approach shall be planned using the best approach capability, normally CAT 3 DUAL, and all available automated systems subject to aircraft status. The following minimum autoflight requirements shall be observed:

	Autoland	Auto-rollout	A/THR	Auto-callout
CAT 3B	Required	Required	Required	Required
CAT 3A	Required	Preferred	Required	Required
CAT 2	Preferred (1)	Preferred	Preferred	Preferred

Note: *(1) If manual landing is required, autopilot shall be disengaged by 80 ft RA.*

MINIMA

Port page and Part A 8.4.1 refers.

DH	DH on PERF APPR page
With DH	Set DH from Port Page
NO DH	Set "NO" (1)

Note: (1) This will generate an autocall of "100", and there will be no "Minimum" call.

BRIEFING

The normal arrival briefing should be supplemented with:

- Confirm LVP in force (clearance to fly a Cat 2/3 approach satisfies this requirement).
- A review of the LWMO and autoland requirements on the Port Page.
- For autoland, confirmation that the wind is within the autoland limits.
- The category of approach to be flown.
- Reversion capability.
- A review of task sharing, standard calls and the actions in the event of a missed approach.

ALERT HEIGHT

The alert height is 200 ft RA. FCTM NO-150 refers.

AUTOMATIC APPROACH AND LAND EVENT SEQUENCE

RAD ALT / ft	EVENT
700	ILS frequency and course frozen in receiver.
≤400	Land mode engages. 'LAND' annunciated on the FMA. This mode can only be disengaged by selecting Go-around.
200	Alert Height. CAT 3 DUAL and CAT 3 SINGLE annunciations are frozen. A failure below this height causing a downgrade of the aircraft's capability would not cause any annunciation change on the FMA.
≤50	Flare mode engages. 'FLARE' annunciated on FMA.
≤40	A/THR Retard mode engages commanding idle thrust. Alignment with centreline (not annunciated).
10	Autocall "Retard."
0	Rollout mode engages. 'ROLLOUT' annunciated on FMA.

FINAL APPROACH AND LANDING

GENERAL

During the approach, the PM shall remain head down throughout until taxi speed is achieved.
Landing lights should not be used during low visibility approaches.

REVERSION

If LAND green is not annunciated by 350 ft RA, a go-around is mandatory unless there are sufficient visual references.
For any system fault that does not incur a landing capability downgrade on ECAM STATUS or FMA, the fault shall be checked against the table in QRH OPS.04 that lists the equipment required for the various landing capabilities.
If a reversion to a degraded approach capability occurs and the RVR is within limits for the approach to be continued with the new capability:

- Above 1 000 ft AAL, complete ECAM actions, amend the DH in the PERF APPR page and continue the approach.
- Below 1 000 ft AAL, a go-around is recommended.

If a reversion to a degraded approach capability occurs and the RVR is below the minima for the new approach capability:

- Above 1 000 ft AAL, the approach may be continued to 1 000 ft in anticipation of an improvement in RVR. Complete ECAM actions, amend the DH in the PERF APPR page and continue the approach.
- Below 1 000 ft AAL, a go-around is mandatory.

The autocall at 1 000 ft RA may be utilized, when appropriate, to meet the above requirements.

BELOW THE ALERT HEIGHT

As a general rule, in Cat 3 DUAL fail operational mode, a single failure that does not illuminate the AUTOLAND warning light does not require a go-around. Unless there are sufficient visual references, a go-around is mandatory:

- If the AUTOLAND warning light illuminates.
- If during an autoland, FLARE is not annunciated by 30 ft RA. In this case, the PM shall call "No flare."

AFTER LANDING

If visual reference is lost after touchdown, a go-around should not be attempted. When clearing the runway, the PM should make reference to the airport chart for taxiing in.
Complete the After Landing Procedures once clear of the runway and before commencing taxi in.

PILOT INCAPACITATION

In the event of pilot incapacitation the approach may be continued as long as the PFD annunciates Cat 2 or better. The pilot incapacitation checklist need not be actioned until after completion of the landing roll.

AUTOLAND OPERATIONS ON RUNWAYS NOT APPROVED FOR LWMO, OR WHEN LVP ARE NOT IN FORCE

Weather conditions must meet Cat 1 ILS RVR requirements or better. Confirm AUTOLAND is approved on the Port Page. Insert the Cat 1ILS minima as the MDA in the MCDU PERF APPR page. LVO procedures apply.

TASK SHARING FOR LVO

	RAD ALT	PF	PM (1)
	350	• Announce "Land green" when displayed on FMA. • Check ILS course on PFD. • Commence outside scanning.	
WITH DH	DH + 100	• Announce "Check."	• Monitor auto callout "Hundred Above."
	DH	• Announce "Continue" or "Go-around, Flaps" as appropriate and execute.	• Monitor auto callout "Minima."
NO DH	100	• If no failure detected, announce "Continue."	• Monitor auto callout "One Hundred."

Continued on the following page

Continued from the previous page

	RAD ALT	PF	PM (1)
	30		• Monitor auto callout. • Announce "Flare" when displayed on FMA. • Monitor thrust reduction and flare by reference to instruments.
	10	• Retard thrust levers to idle. • Monitor lateral guidance by external reference. • Select and control reverse thrust. • Disengage the APs at the end of the rollout.	• Monitor engine parameters. • Announce "Rollout" when displayed on FMA. • Check and call "Spoilers, Reverse green, Decel." • Announce "Seventy knots."

Note: (1) For Cat 2 approaches, PM must make the calls if the autocallout function is inoperative.

Intentionally left blank

HOT WEATHER GROUND CONDITIONS

Applicable to: ALL

The Bleed duct overheat detection sensing units are prone to deterioration in a high humidity, high temperature environment.
This leads to a gradual lowering of the overheat detector trigger temperature.
On ground, high temperature conditions may cause overheating to be spuriously detected around the bleed ducts in the wings, resulting in AIR L(R) WING LEAK warnings.
CX Engineering monitor individual aircraft displaying the above noted trend. In some cases, they will raise a NTC in the Aircraft Maintenance Logbook requesting the crew to perform the following procedure in order to minimize or avoid spurious warnings.

- **These recommendations apply when the OAT is >30 C and the expected transit time is greater than 1 hour.**

  1. Do not retract flaps after landing to less than Flap 1 position.

     Note: This will leave the leading edge slats partially extended and the flaps in the 1+F position.

  2. Ensure that the required flap setting for the subsequent takeoff is entered into the MCDU PERF T/O page.
  3. After engine start, set the flap lever to the required takeoff flap setting.

Note: It is permissible to leave the flap at position 1 even when the crew are not in transit with the aircraft. During the transit period, for safety reasons, obtain ground clearance before moving the flap lever.

Intentionally left blank

TYPHOON CONDITIONS

Applicable to: ALL

Typhoon conditions are associated with very gusty winds and it is the gusts that must be catered for. Large airspeed changes can occur in these conditions. An initial approach speed of VLS +20 kt to 30 kt is acceptable.

On the final stages of the approach consideration should be given to the fact that VAPP takes into account a wind correction as well as minimum ground speed. Speeds significantly in excess of the VAPP at the threshold of a limited length runway may compromise landing distance required. In this case a go-around should be initiated.

It is recommended that approaches in very gusty conditions be flown in MANUAL THRUST (to dampen harsh thrust reactions) and MANAGED SPEED (to benefit from the in built protections of the FMGS).

MAXIMUM WIND FOR LANDING

Applicable to: ALL

Landings should not be made at airports where frequent gusts of 55 kt or greater are being experienced. This reduces the potential damage to aircraft by wind-blown ground equipment.

LIM-11-PLP PRELIMINARY PAGES

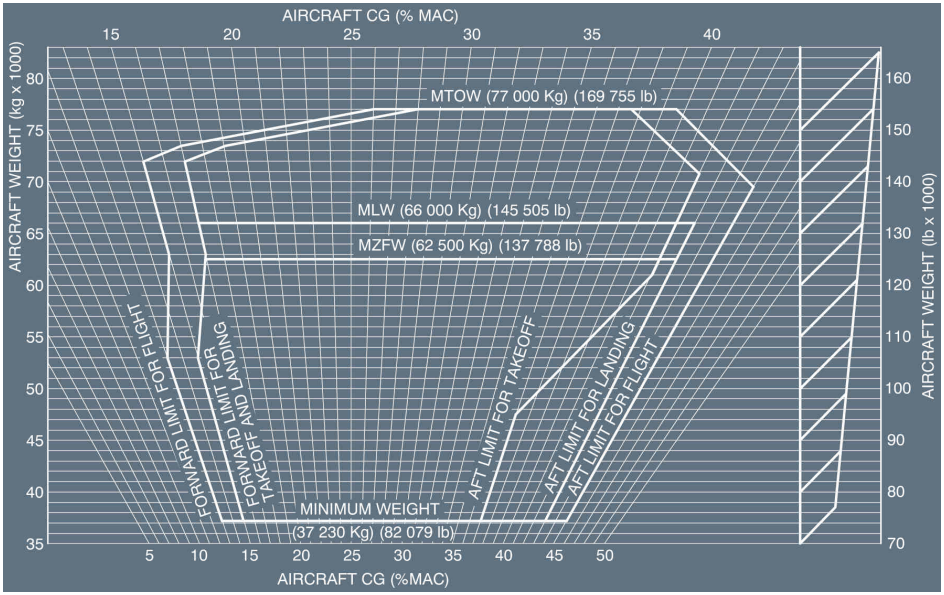
TABLE OF CONTENTS

Center of Gravity Limits....A
Weight Limitations....B

Intentionally left blank

CENTER OF GRAVITY LIMITS

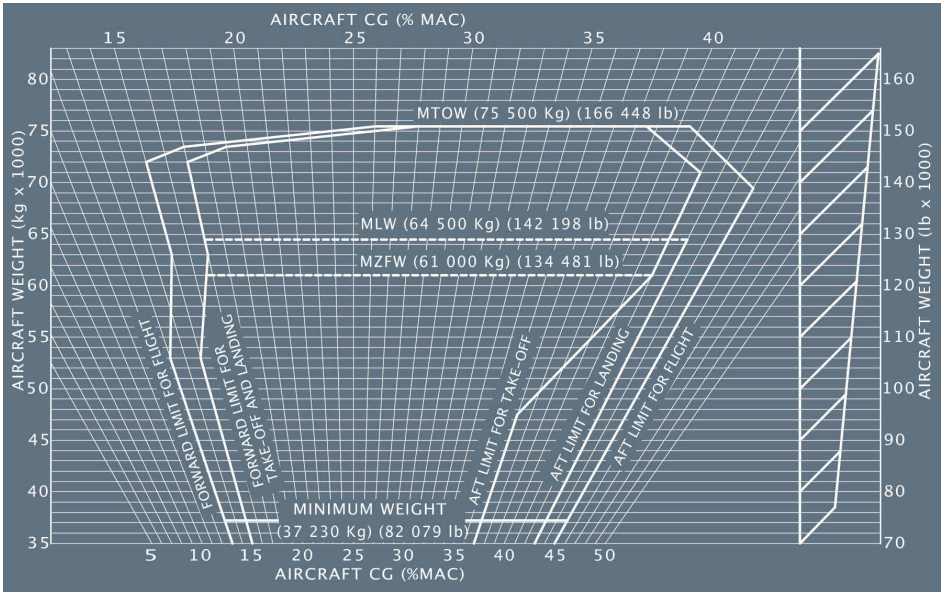
Applicable to: B-HSQ, B-HSR



- CG limits are given in percentage of the reference chord length aft of the leading edge.
- The reference chord length is 4.193 m (13.76 ft). It is 16.31 m (53.51 ft) aft of the aircraft nose.
- The CG must always be within these limits, regardless of fuel load.

CENTER OF GRAVITY LIMITS

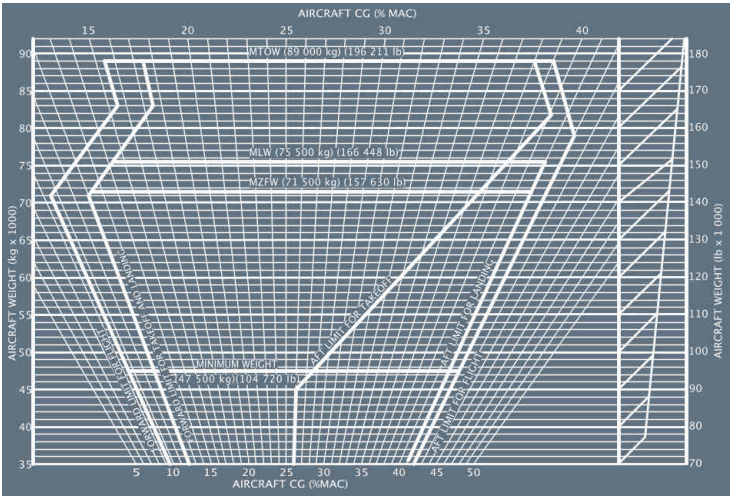
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP



- CG limits are given in percentage of the reference chord length aft of the leading edge.
- The reference chord length is 4.193 m (13.76 ft). It is 16.31 m (53.51 ft) aft of the aircraft nose.
- The CG must always be within these limits, regardless of fuel load.

CENTER OF GRAVITY LIMITS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



- CG limits are given in percentage of the reference chord length aft of the leading edge.
- The reference chord length is 4.193 m (13.76 ft). It is 20.58 m (67.53 ft) aft of the aircraft nose.
- The CG must always be within these limits, regardless of fuel load.

WEIGHT LIMITATIONS

Applicable to: B-HSQ, B-HSR

Maximum taxi weight..... 77 400 kg (170 637 lb)
Maximum takeoff weight (brake release)..... 77 000 kg (169 755 lb)
Maximum landing weight..... 66 000 kg (145 505 lb)
Maximum zero fuel weight..... 62 500 kg (137 788 lb)
Minimum weight..... 37 230 kg (82 079 lb)

In exceptional cases (in flight turn back or diversion), an immediate landing at weight above maximum landing weight is permitted, provided the pilot follows the overweight landing procedure.

WEIGHT LIMITATIONS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

Maximum taxi weight..... 75 900 kg (167 330 lb)
Maximum takeoff weight (brake release)..... 75 500 kg (166 448 lb)

Maximum landing weight.....64 500 kg (142 198 lb)
Maximum zero fuel weight.....61 000 kg (134 481 lb)
Minimum weight.....37 230 kg (82 079 lb)
In exceptional cases (in flight turn back or diversion), an immediate landing at weight above maximum landing weight is permitted, provided the pilot follows the overweight landing procedure.

WEIGHT LIMITATIONS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Maximum taxi weight.....89 400 kg (197 093 lb)
Maximum takeoff weight (brake release).....89 000 kg (196 211 lb)
Maximum landing weight.....75 500 kg (166 449 lb)
Maximum zero fuel weight.....71 500 kg (157 630 lb)
Minimum weight.....47 500 kg (104 720 lb)
In exceptional cases (in flight turn back or diversion), an immediate landing at weight above maximum landing weight is permitted, provided the pilot follows the overweight landing procedure.

Wind for takeoff and landing:

Maximum demonstrated crosswind.....38 kt (gust included)

Note: *1. The maximum demonstrated crosswind value is not an Airplane Flight Manual (AFM) limitation : It is the maximum crosswind condition experienced during the aircraft certification campaign. Airbus recommends that operators should not intentionally operate in crosswinds that exceed this value.*

2. For crosswind value on contaminated runway Refer to PRO-SUP-91-50 Crosswind.

Maximum tailwind for takeoff..... 15 kt

Maximum tailwind for landing ..... 15 kt

Note: - *The maximum tailwind for automatic landing and rollout remains 10 kt.*

- *FLAPS FULL selection is recommended for landing with 15 kt tailwind.*

Wind for passenger/cargo door operation:

Maximum wind for passenger door operation:..... 65 kt

Maximum wind for cargo door operation: 40 kt (or 50 kt, if the aircraft nose is oriented into the wind, or the cargo door is on the leeward side).

The cargo door must be closed, before the wind speed exceeds 65 kt.

Intentionally left blank

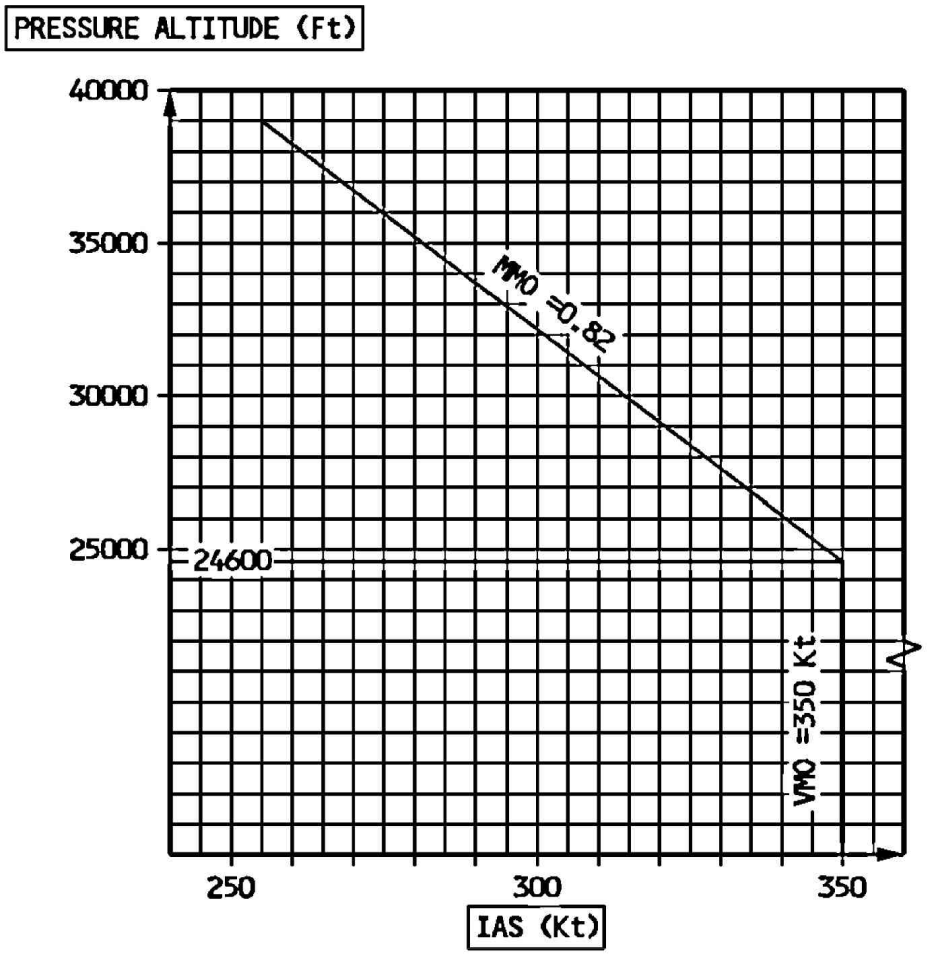
MAXIMUM OPERATING SPEED VMO/MMO

Applicable to: ALL

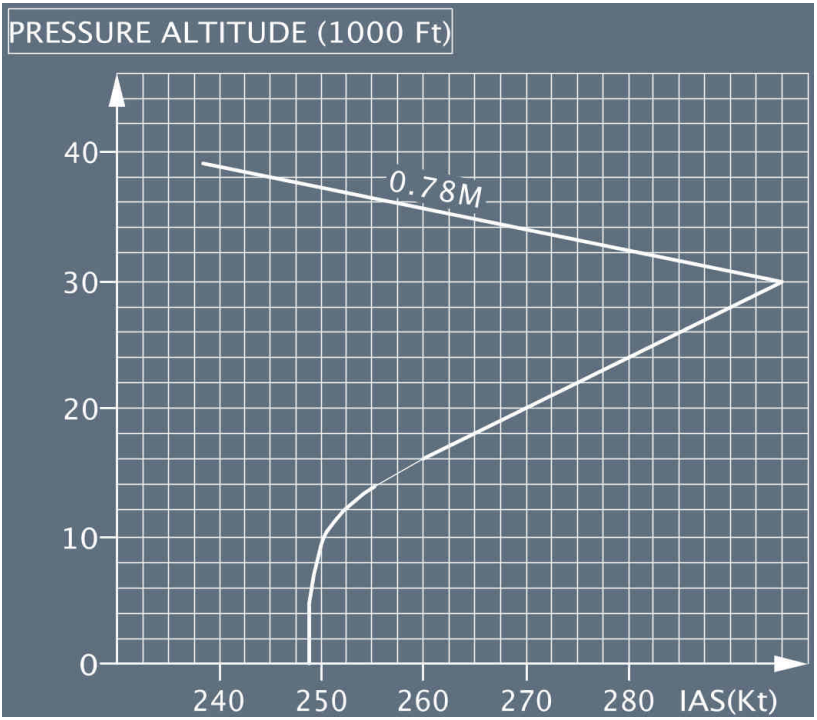


The maximum operating limit speed VMO/MMO may not be deliberately exceeded in any regime of flight.

MAXIMUM DESIGN MANOEUVERING SPEED VA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

(Applies in alternate or direct flight control laws only).



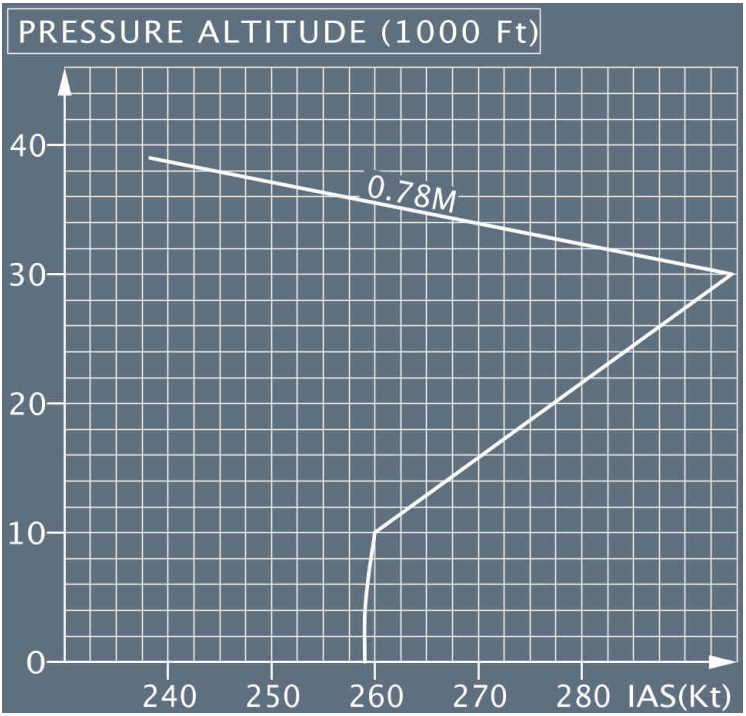
If alternate or direct law is active, full ailerons and rudder application should be confined to speeds below VA.
If alternate or direct law is active manoeuvres involving angle of attack near stall should be confined to speeds below VA.

CAUTION	Rapid and large alternating control inputs, especially in combination with large changes in pitch, roll, or yaw (e.g. large sideslip angles) may result in structural failures at any speed, even below VA.

MAXIMUM DESIGN MANOEUVERING SPEED VA

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

(Applies in alternate or direct flight control laws only).

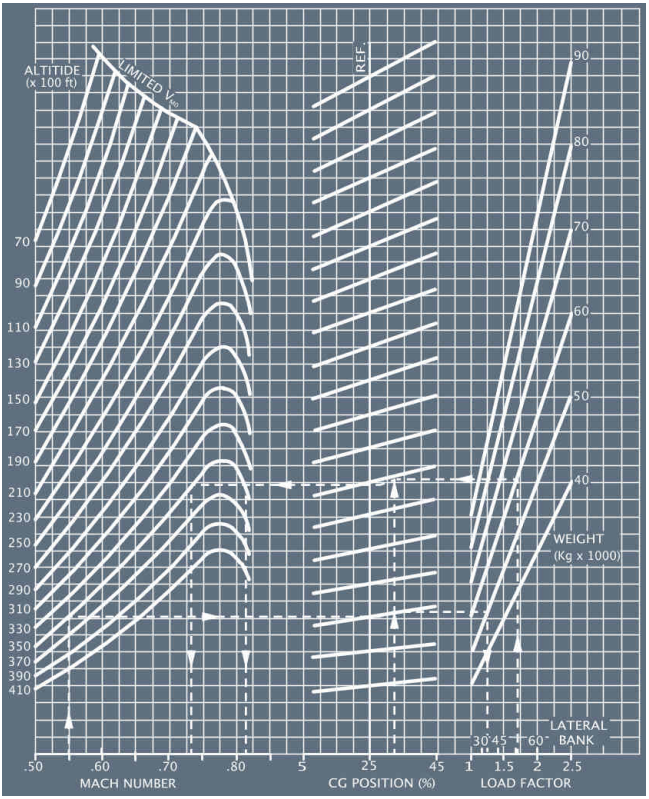


If alternate or direct law is active, full ailerons and rudder application should be confined to speeds below VA.
If alternate or direct law is active manoeuvres involving angle of attack near stall should be confined to speeds below VA.

CAUTION	Rapid and large alternating control inputs, especially in combination with large changes in pitch, roll, or yaw (e.g. large sideslip angles) may result in structural failures at any speed, even below VA.

BUFFET ONSET

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

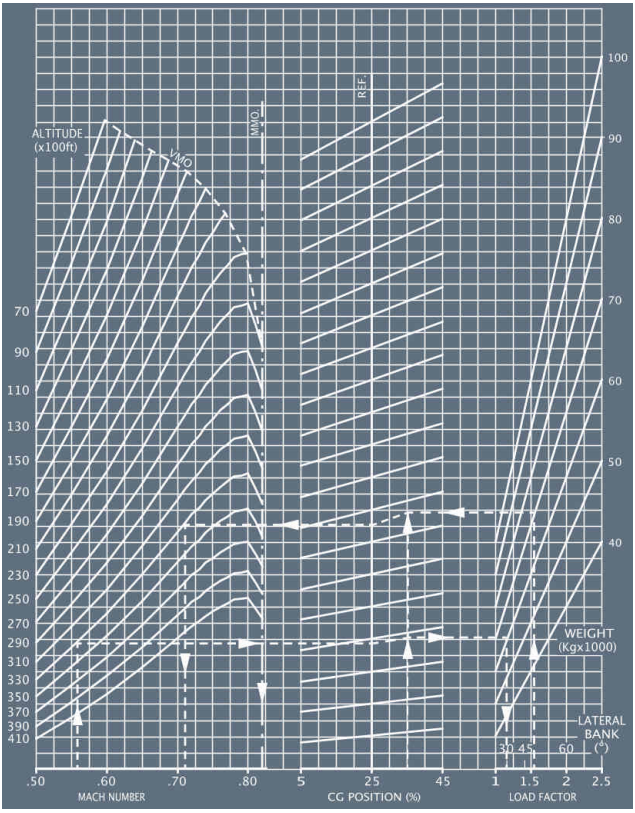


Examples:

1. Determine Maximum Bank Angle limited by buffet:
   DATA : M = 0.55, FL = 350, CG = 31 %, WEIGHT = 50 000 kg
   RESULT: load factor = 1.25 g or 35 ° bank
2. Determine low and high speed limited by buffet:
   DATA : 52 ° bank or 1.7 g, WEIGHT = 60 000 kg, CG = 31 %, FL = 350
   RESULT: M = 0.73 (low speed buffet) and M = 0.81 (high speed buffet).

BUFFET ONSET

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



Examples:

1. Determine Maximum Bank Angle limited by buffet:
   DATA : M = 0.56, FL = 330, CG = 35 %, WEIGHT = 60 000 kg
   RESULT: load factor = 1.2 g or 30 ° bank
2. Determine low and high speed limited by buffet:
   DATA : 48 ° bank or 1.55 g, WEIGHT = 70 000 kg, CG = 35 %, FL = 330
   RESULT: M = 0.71 (low speed buffet) and M = 0.82 (high speed buffet).

MINIMUM CONTROL SPEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Maximum speed with landing gear extended (VLE).....280 kt /M .67
Maximum speed at which the landing gear may be extended (VLO extension) ..... 250 kt
Maximum speed at which the landing gear may be retracted (VLO retraction) ..... 220 kt
Maximum altitude at which the landing gear may be extended..... 25 000 ft

MAXIMUM TIRE SPEED

Applicable to: ALL

Ground speed..... 195 kt

WINDSHIELD WIPERS IN USE

Applicable to: ALL

Maximum speed..... 230 kt

COCKPIT WINDOW OPEN

Applicable to: ALL

Maximum speed..... 200 kt

TAXI SPEED

Applicable to: ALL

When the taxi weight is higher than 76 000 kg (167 550 lb), do not exceed a taxi speed of 20 kt during a turn.

STALLING SPEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following graphs serve to determine the VS according to the configuration.

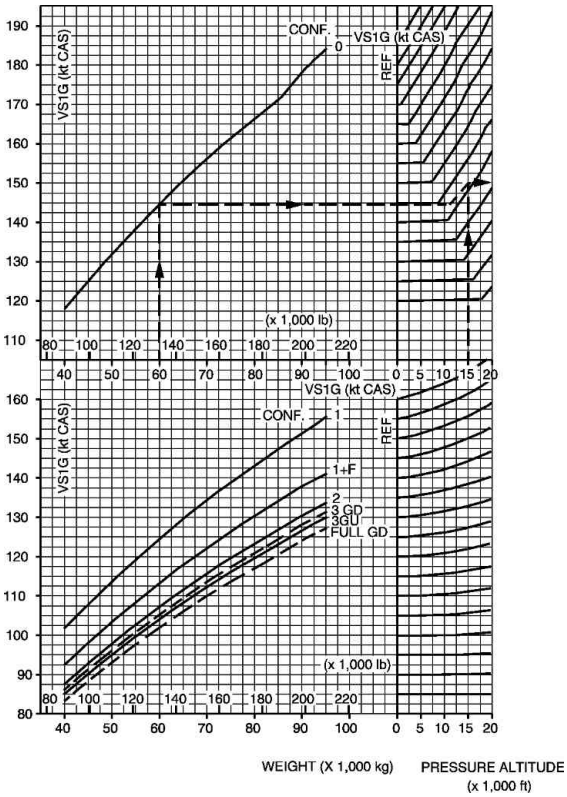
These graphs have been established for

- Basic forward CG
  - 23 % CG location in clean configuration
  - 25 % CG location in takeoff, approach and landing configuration
- Alternate forward CG
  - forward CG limit. *Refer to LIM-11 Center of Gravity Limits*.

In most cases the CG location remains within the CG envelope below. Consequently the basic forward CG must be retained for any performance determination.
In some rare cases, if more forward CG is anticipated during any part of the flight, the alternate forward CG must be retained for any performance determination.

STALLING SPEEDS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



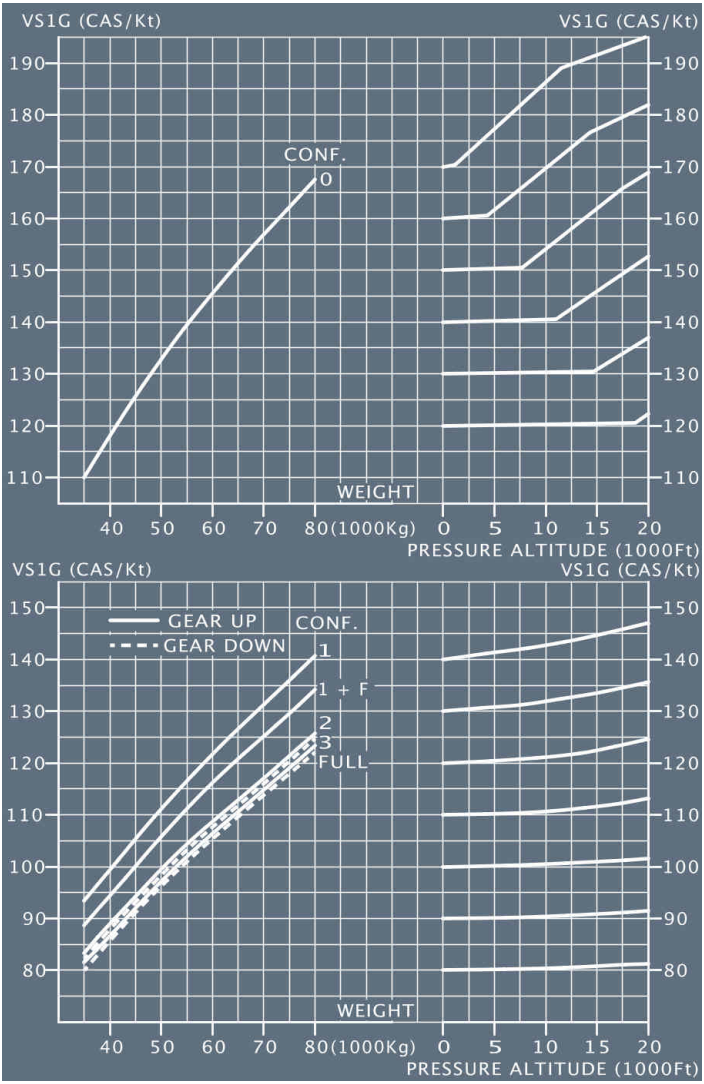
EXAMPLE :

DATA : 60 000 kg (132 276 lb), pressure altitude 15 000 ft, clean configuration.

RESULT : VS1G CAS = 150 kt

STALLING SPEEDS (BASIC FORWARD C.G.)

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR



STALLING SPEEDS (ALTERNATE FORWARD C.G.)

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Intentionally left blank

RAM AIR INLET

Applicable to: ALL

Only open if differential pressure is lower than 1 PSI.

AIR CONDITIONING WITH LP GROUND UNIT

Applicable to: ALL

- Do not use conditioned air simultaneously from packs and LP ground unit (to avoid chattering of the non return valves).
- Airflow supplied by the ground cart shall not exceed 1.2 kg/s (2.60 lb/s).

AIR CONDITIONING WITH HP GROUND UNIT

Applicable to: ALL

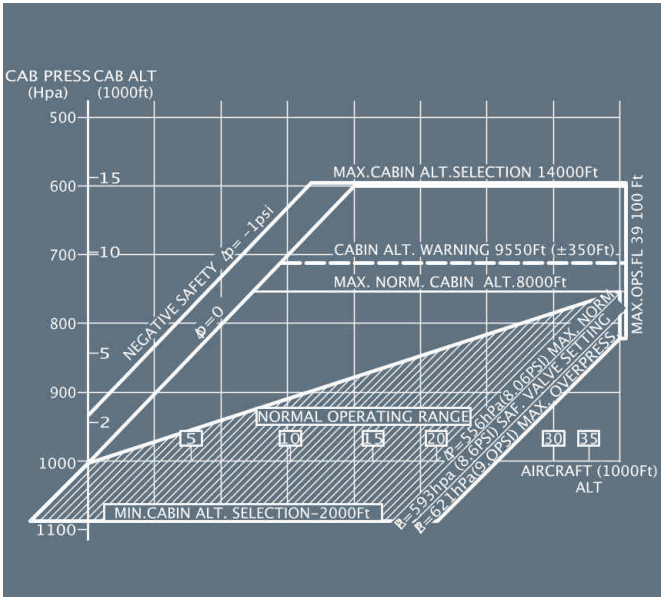
Do not use HP ground unit when APU supplies bleed air to avoid bleed system damage.

Intentionally left blank

CABIN PRESSURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

Maximum positive differential pressure..... 8.6 PSI
Maximum negative differential pressure..... -1 PSI

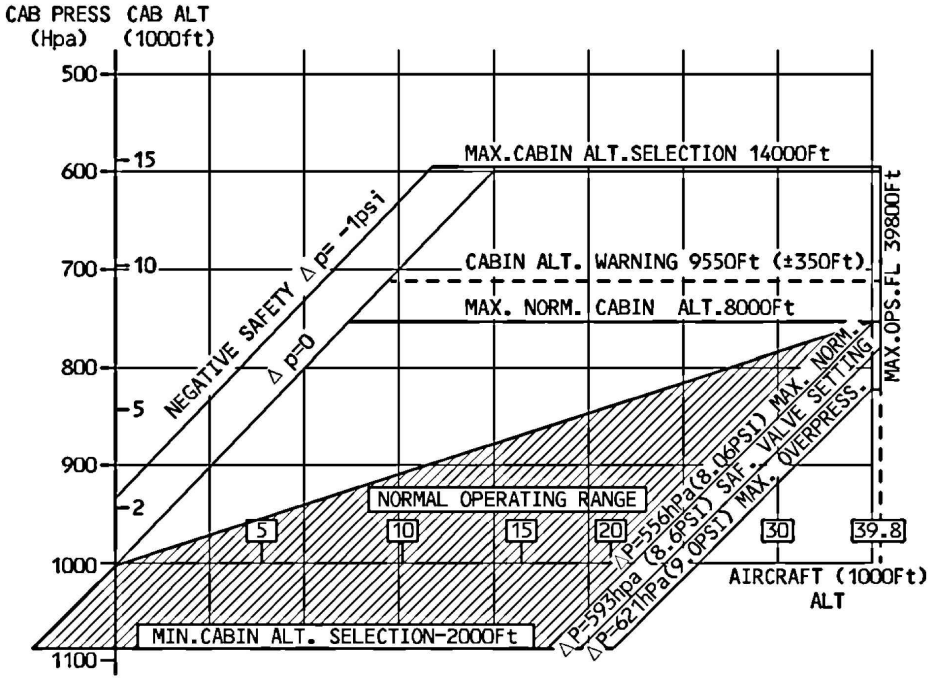


Note: *Max Δp and safety valve setting tolerance = ± 7 hPa (0.1 PSI)*

CABIN PRESSURE

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

Maximum positive differential pressure..... 8.6 PSI
Maximum negative differential pressure..... -1 PSI



Note: *Max Δp and safety valve setting tolerance = ± 7 hPa (0.1 PSI)*

AVIONICS VENTILATION

Applicable to: ALL

During ground operations, limit the aircraft electric power supply with avionics ventilation system in normal configuration as follows :

OAT = 49 °C	no limitation
OAT = 55 °C	time limit 2 h
OAT = 60 °C	time limit 1 h
OAT = 64 °C	time limit 1/2 h

AUTO PILOT FUNCTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ

Minimum height for use of autopilot on takeoff with SRS mode..... 100 ft AGL

(An internal FMGS logic prevents the autopilot from engaging during the 5 s after liftoff).

Minimum height for use of the autopilot in:

- Straight-in non precision approach..... applicable MDA (MDH)
- Straight-in LNAV/VNAV approach..... applicable DA
- Circling approach..... applicable MDA - 100 ft (or MDH - 100 ft)
- ILS approach when CAT2 or CAT3 is not displayed on the FMA ..... 160 ft AGL
- Go-around (AP or FD engagement) ..... 100 ft AGL
- All other phases..... 500 ft AGL

Use of the AP or FD in OPEN DES or DES mode is not permitted in approach, unless the FCU altitude is set to, or above, MDA (MDH) or 500 ft, whichever is the highest.

AUTO PILOT FUNCTION

Applicable to: B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP

Minimum height for use of autopilot on takeoff with SRS mode..... 100 ft AGL

(An internal FMGS logic prevents the autopilot from engaging during the 5 s after liftoff).

Minimum height for use of the autopilot in:

- Straight-in non precision approach..... applicable MDA (MDH)
- Straight-in LNAV/VNAV approach..... applicable DA
- Circling approach..... applicable MDA - 100 ft (or MDH - 100 ft)
- ILS approach when CAT2 or CAT3 is not displayed on the FMA..... 160 ft AGL
- PAR approach (Precision Approach Radar) ..... 250 ft AGL

  Use of the AP and/or FD is authorized in PAR approach, with HDG V/S or TRK FPA.
- Go-around (AP or FD engagement) ..... 100 ft AGL
- All other phases..... 500 ft AGL

Use of the AP or FD in OPEN DES or DES mode is not permitted in approach, unless the FCU altitude is set to, or above, MDA (MDH) or 500 ft, whichever is the highest.

AUTO PILOT FUNCTION

Applicable to: B-HTD, B-HTE, B-HTF

Minimum height for use of autopilot on takeoff with SRS mode..... 100 ft AGL

AUTO PILOT FUNCTION

Applicable to: B-HSQ, B-HSR

Minimum height for use of autopilot on takeoff with SRS mode..... 100 ft AGL

(An internal FMGS logic prevents the autopilot from engaging during the 5 s after liftoff).

Minimum height for use of the autopilot in:
- Straight-in non precision approach..... applicable minimum
- Circling approach..... applicable circling minimums - 100 ft
- ILS approach when CAT2 or CAT3 is not displayed on the FMA ..... 160 ft AGL

- PAR approach (Precision Approach Radar) ..... 250 ft AGL
  Use of the AP and/or FD is authorized in PAR approach, with HDG V/S or TRK FPA.
- Go-around (AP or FD engagement) ..... 100 ft AGL
- All other phases..... 500 ft AGL

Use of the AP or FD in OPEN DES or DES mode is not permitted in approach, unless the FCU altitude is set to, or above, MDA (MDH) or 500 ft, whichever is the highest.

AUTOTHRUST FUNCTION

Applicable to: ALL

Use of the autothrust is approved with, or without, AP/FD in selected or managed mode.

FLIGHT MANAGEMENT FUNCTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

FMGS lateral and vertical navigation has been certified for after takeoff, en route, and terminal area operations, for instrument approach procedures (except ILS, LOC, LOC-BC, LDA, SDF and MLS), and for missed approach procedures.
RNP accuracy with GPS PRIMARY, or radio updating, has been demonstrated to be:

	With AP ON in NAV	With AP OFF and FD ON in NAV	With AP OFF and FD OFF
En route	2 nm	2 nm	2 nm
In terminal area	0.5 nm	0.52 nm	0.52 nm
In approach	0.3 nm	0.3 nm with GPS 0.37 nm without GPS	Not authorized

Without GPS PRIMARY (or GPS deselected or inoperative), the accuracy has been demonstrated, provided the appropriate RNP value is checked or entered on the MCDU, and HIGH accuracy is displayed.
Without GPS PRIMARY (or GPS deselected or inoperative), navigation accuracy is a function of ground radio NAVAID infrastructure, or elapsed time since the last radio update.
The FMGS is also certified for navigation within BRNAV, PRNAV, RNP-4 and RNP-10 airspace. RNP 10 oceanic/remote area operations are approved with GPS PRIMARY, or without GPS PRIMARY (or GPS deselected or inoperative), provided time limitations in IRS only navigation (acceptable to operational authorities), are established.
FMGS approval is based on the assumption that the navigation database has been validated for intended use.
Obstacle clearance and adherence to airspace constraints remains the flight crew's responsibility.
Fuel, time predictions/performance information is provided for advisory purposes only.

NAV mode may be used after takeoff, provided FMGS runway updating has been checked.

FLIGHT MANAGEMENT FUNCTION

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

FMGS lateral and vertical navigation has been certified for after takeoff, en route, and terminal area operations, for instrument approach procedures (except ILS, LOC, LOC-BC, LDA, SDF and MLS), and for missed approach procedures.

RNP accuracy with GPS PRIMARY, or radio updating, has been demonstrated to be:

	With AP ON in NAV	With AP OFF and FD ON in NAV	With AP OFF and FD OFF
En route	1 nm	1 nm	1.1 nm
In terminal area	0.5 nm	0.51 nm	0.51 nm
In approach	0.3 nm	0.3 nm	Not authorized

Without GPS PRIMARY (or GPS deselected or inoperative), the accuracy has been demonstrated, provided the appropriate RNP value is checked or entered on the MCDU, and HIGH accuracy is displayed.

Without GPS PRIMARY (or GPS deselected or inoperative), navigation accuracy is a function of ground radio NAVAID infrastructure, or elapsed time since the last radio update.

The FMGS is also certified for navigation within BRNAV, PRNAV, RNP-4 and RNP-10 airspace. RNP 10 oceanic/remote area operations are approved with GPS PRIMARY, or without GPS PRIMARY (or GPS deselected or inoperative), provided time limitations in IRS only navigation (acceptable to operational authorities), are established.

FMGS approval is based on the assumption that the navigation database has been validated for intended use.

Obstacle clearance and adherence to airspace constraints remains the flight crew's responsibility.

Fuel, time predictions/performance information is provided for advisory purposes only.

NAV mode may be used after takeoff, provided FMGS runway updating has been checked.

TAKEOFF IN GPS PRIMARY

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

For certain airports, where the difference between the local coordinate system and WGS 84 (geodesic standard used by GPS, FMS) is not negligible, an incorrect NAV guidance may occur after takeoff.

GPS must be deselected for takeoff from these airports, until a safe altitude is reached.

TAKEOFF IN GPS PRIMARY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

For certain airports, where the difference between the local coordinate system and WGS 84 (geodesic standard used by GPS, FMS) is not negligible, a map shift may occur after takeoff. GPS must be deselected for takeoff from these airports, until a safe altitude is reached.

USE OF NAV AND FINAL APP MODES FOR NON-PRECISION APPROACH

Applicable to: ALL

NAV, or NAV and FINAL APP mode may be used for VOR, VOR/DME, NDB, NDB/DME or RNAV (including GPS) approach, but not for ILS, LOC, LOC-BC, LDA, SDF, or MLS final approach.
For instrument procedures not coded in the WGS 84 coordinate system, the GPS must be deselected, unless the shift between the local coordinate system and the WGS 84 is found acceptable for the intended operation.

Note: *1. The assesment of this shift can be done:*
- *In flight, monitoring the NAVAID raw data in non RNAV procedures,*
- *On ground performing a GPS survey of the procedure waypoints.*

2. RNAV (GPS) and RNP RNAV approach procedures require WGS 84 coordinates and GPS.

FINAL APP mode guidance capability with GPS PRIMARY has been demonstrated down to MDH/DH (barometric) 250 ft.

VOR, VOR/DME, NDB or NDB/DME approach procedures may be performed, in NAV, or NAV and FINAL APP mode, provided AP or FD is used, and:
- GPS PRIMARY is available. In this case, the reference NAVAID may be unserviceable, or the airborne radio equipment may be inoperative, or not installed, provided operational approval is obtained.
- Without GPS PRIMARY:
  - The reference NAVAID and the corresponding airborne equipment is serviceable, tuned, and monitored during the approach, or
  - The radio NAVAID coverage supports the RNP value, specified for the approach procedure, and an operational approval is obtained.

For GPS approach, GPS PRIMARY must be available.
RNAV approach without GPS PRIMARY may be performed only if the radio NAVAID coverage supports the RNP value and HIGH accuracy is displayed on the MCDU with the specified RNP, and operational approval is obtained.

NAV mode may be used in the terminal area, provided:
- GPS PRIMARY is available, or
- HIGH accuracy is displayed, and the appropriate RNP is checked or entered on the MCDU, or
- NAVAID raw data is monitored.

NON-PRECISION APPROACHES WITH ENGINE-OUT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

If one engine is inoperative, it is not permitted to use the autopilot to perform NPAs in the following modes: FINAL APP, NAV V/S, NAV/FPA.
Only FD use is permitted.

NON-PRECISION APPROACHES WITH ENGINE-OUT

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

No longer applicable

CATEGORY II

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Minimum decision height..... 100 ft AGL
At least one autopilot must be engaged in APPR mode, and CAT 2, CAT 3 SINGLE or CAT 3 DUAL must be displayed on the FMA.
If the flight crew performs an automatic approach without autoland, the autopilot must be disengaged no later than at 80 ft AGL.

CATEGORY II

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Minimum decision height..... 100 ft AGL
At least one autopilot must be engaged in APPR mode, and CAT 2, CAT 3 SINGLE or CAT 3 DUAL must be displayed on the FMA.
If the flight crew performs an automatic approach without autoland, the autopilot must be disengaged no later than at 80 ft AGL.

MAXIMUM WIND CONDITIONS FOR CAT II AUTOMATIC APPROACH WITHOUT AUTOLAND

Head wind	:	40 kt
Tail wind	:	10 kt
Cross wind	:	25 kt

CATEGORY III FAIL PASSIVE (SINGLE)

Applicable to: ALL

Minimum decision height..... 50 ft
At least one autopilot must be engaged in APPR mode, and CAT 3 SINGLE or CAT 3 DUAL must be displayed on the FMA.
A/THR must be used in selected or managed speed.

CATEGORY III FAIL OPERATIONAL (DUAL)

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

A/THR must be used in selected or managed speed.
Alert height..... 100 ft

- CAT III with DH :
  Minimum decision height..... 25 ft
  2 autopilots must be engaged in APPR mode and CAT 3 DUAL must be displayed on the FMA.
- CAT III without DH :
  2 autopilots must be engaged in APPR mode and CAT 3 DUAL must be displayed on the FMA.
  Minimum Runway Visual Range..... 75 m

CATEGORY III FAIL OPERATION (DUAL)

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

A/THR must be used in selected or managed speed.
Alert height..... 100 ft

- CAT III with DH :
  Minimum decision height..... 22 ft
  2 autopilots must be engaged in APPR mode and CAT 3 DUAL must be displayed on the FMA.
- CAT III without DH :
  2 autopilots must be engaged in APPR mode and CAT 3 DUAL must be displayed on the FMA.
  Minimum Runway Visual Range..... 75 m

ENGINE OUT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

CAT II and CAT III fail passive autoland are only approved in configuration FULL, and if engine-out procedures are completed before reaching 1 000 ft in approach.

ENGINE OUT

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

CAT II and CAT III fail passive autoland are only approved in configuration 3 and FULL, and if engine-out procedures are completed before reaching 1 000 ft in approach.

MAXIMUM WIND CONDITIONS FOR CAT II OR CAT III AUTOMATIC APPROACH LANDING AND ROLL OUT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Headwind : 30 kt
Tailwind : 10 kt
Crosswind : 20 kt

Note: Wind limitation is based on the surface wind reported by ATC. If the wind displayed on ND exceeds the above-noted autoland limitations, but the tower reports a surface wind within the limitations, then the autopilot can remain engaged. If the tower reports a surface wind beyond limitations, only CAT I automatic approach without autoland can be performed.

MAXIMUM WIND CONDITIONS FOR CAT III AUTOMATIC APPROACH OR AUTOMATIC LANDING AND AUTOMATIC ROLL OUT

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Headwind : 30 kt

Tailwind : 10 kt

Crosswind : 20 kt

Note: Wind limitation is based on the surface wind reported by ATC. If the wind displayed on the ND exceeds the above-noted autoland limitations, but the tower reports surface wind within the limitations, then the autopilot can remain engaged. If the tower reports a surface wind that exceeds the limitations, only CAT II automatic approach without autoland can be performed provided wind conditions are within the limitations quoted on Refer to LIM-22-20 Category II. Otherwise, only CAT I automatic approach without autoland can be performed.

AUTOMATIC LANDING

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

CAT II and CAT III autoland are approved in CONF 3 and CONF FULL.

Automatic landing is demonstrated:
- With CAT II and CAT III ILS beam.
- With slope angle within (-2.5 °, -3.15 °) range.
- At or below the maximum landing weight.
- For airport elevation at or below 6 500 ft.
- At approach speed (VAPP) = VLS + wind correction.
  Minimum wind correction 5 kt, maximum wind correction 15 kt.

Automatic rollout performance has been approved on dry and wet runways, but performance on snow-covered or icy runways has not been demonstrated.

AUTOMATIC LANDING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI

CAT II and CAT III autoland are approved in CONF 3 and CONF FULL.

Automatic landing is demonstrated :
- With CAT II and CAT III ILS beam.
- With slope angle within (–2.5 °, –3.15 °) range.
- For airport elevation at or below 2 500 ft.
- At or below the maximum landing weight.
- At approach speed (VAPP) = VLS + wind correction.
  Minimum wind correction 5 kt ; maximum windcorrection15 kt.

Automatic rollout performance has been approved on dry and wet runways, but performance on snow-covered or icy runways has not been demonstrated.

AUTOMATIC LANDING

Applicable to: B-HTD, B-HTE, B-HTF

CAT II and CAT III autoland are approved in CONF 3 and CONF FULL.

Automatic landing is demonstrated:
- With CAT II and CAT III ILS beam
- With slope angle within (-2.5 °, -3.15 °) range
- For airport elevation at or below 2 500 ft
- At or below the maximum landing weight
- At approach speed (VAPP) = VLS + wind correction
  Minimum wind correction 5 kt ; maximum wind correction 15 kt.

Automatic rollout performance has been approved on dry and wet runways, but performance on snow-covered or icy runways has not been demonstrated.
During automatic rollout with one engine inoperative or one thrust reverser inoperative, the use of the thrust reverser is limited to IDLE reverse with a maximum crosswind component of 15 kt

AUTOMATIC LANDING

Applicable to: B-HTG, B-HTH, B-HTI

CAT II and CAT III autoland are approved in CONF 3 and CONF FULL.

Automatic landing is demonstrated:
- With CAT II and CAT III ILS beam
- With slope angle within (-2.5 °, -3.15 °) range
- For airport elevation at or below 5 750 ft
- At or below the maximum landing weight
- At approach speed (VAPP) = VLS + wind correction
  Minimum wind correction 5 kt, maximum wind correction 15 kt.

Automatic rollout performance has been approved on dry and wet runways, but performance on snow-covered or icy runways has not been demonstrated.

During automatic rollout with one engine inoperative or one thrust reverser inoperative, the flight crew can use the remaining thrust reverser, provided that:

- Only IDLE reverse thrust is used
- The crosswind does not exceed 15 kt.

ILS AUTOMATIC LANDING IN CAT I OR BETTER WEATHER CONDITIONS

Applicable to: ALL

The automatic landing system's performance has been demonstrated on runways equipped with CAT II or CAT III ILS approaches. However, automatic landing in CAT I or better weather conditions is possible on CAT I ground installations or when ILS sensitive areas are not protected, if the following precautions are taken:

- The airline has checked that the ILS beam quality and the effect of terrain profile before the runway have no adverse effect on AP/FD guidance. In particular, the effect of terrain discontinuities within 300 m before runway threshold must be evaluated.
- The crew is aware that LOC or GS beam fluctuations, independent of the aircraft systems, may occur and the PF is prepared to immediately disconnect the AP and take appropriate action, should unsatisfactory guidance occur.
- At least CAT2 capability is displayed on the FMA, and CAT II/III procedures are used.
- Visual references are obtained at an altitude appropriate to the performed CAT I approach, otherwise go–around is initiated.

AUTOMATIC LANDING IN JOHANNESBURG

Applicable to: ALL
Impacted DU: NONE

Do not perform an automatic landing on the Johannesburg 03R/21L runway.
The flight crew can perform a CAT II automatic approach, but the flight crew must disconnect the AP no later than at 80 ft AGL.

FUEL AND ADDITIVE SPECIFICATIONS

Applicable to: ALL

- See engine manufacturer specification
- Fuel system has been certified for JET A1, JP 8, JET A, JP 5, RT, TS-1, JET B, JP 4 and N°3 JET.

MAXIMUM ALLOWED WING FUEL IMBALANCE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

INNER TANKS (OUTER TANKS BALANCED)

Tank Fuel Quantity (Heavier tank)	Maximum allowed imbalance
Full	1 500 kg (3 306 lb)
4 300 kg (9 479 lb)	1 600 kg (3 527 lb)
2 250 kg (4 960 lb)	2 250 kg (4 960 lb)

The variation is linear between these values (No limitation below 2 250 kg /4 960 lb)

OUTER TANKS

Maximum allowed imbalance	690 kg (1 521 lb)(1)

(1) *Maximum outer wing tank imbalance (one full/one empty) is allowed provided:*

- *Fuel content of one side (outer + inner) is equal to the fuel content of the other side (outer + inner), or*
- *On the side of the lighter outer tank, the inner tank fuel quantity is higher than the opposite inner tank quantity, up to a maximum of 3 000 kg/6 614 lb higher.*

Note: In exceptional conditions (i.e., fuel system failures) the above-mentioned maximum fuel imbalance values may be exceeded without significantly affecting the aircraft handling qualities. The aircraft remains fully controllable in all phases of the flight.

MAXIMUM ALLOWED WING FUEL IMBALANCE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Wing tanks	
Heavy tank content	**Maximum allowed imbalance**
FULL	1 320 kg/2 910 lb
4 000 kg/8 818 lb	1 450 kg/3 196 lb
2 350 kg/5 180 lb (empty on the other side)	2 350 kg/5 180 lb)

Apply linear interpolation between these values (No limitation below 2 350 kg /5 180 lb).

Note: *In exceptional conditions (i.e., fuel system failures) the above-mentioned maximum fuel imbalance values may be exceeded without significantly affecting the aircraft handling qualities. The aircraft remains fully controllable in all phases of the flight.*

FUEL TEMPERATURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

	JET A1/JP 8/N°3 JET	JET A	JP 5	RT	TS-1	JET B	JP 4
MINI	-43 °C	-36 °C (1)	-42 °C	-45 °C	-45 °C	-46 °C	-54 °C
MAXI	54 °C					49 °C	

(1) *For JET A only, if TAT reaches -34 °C, monitor on FUEL SD page that fuel temperature remains higher than -36 °C.*

FUEL TEMPERATURE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

	JET A1/JP 8/N°3 JET	JET A	JP 5	RT	TS-1	JET B	JP 4
MINI	-43 °C	-36 °C (1)	-42 °C	-45 °C	-45 °C	-46 °C	-54 °C
MAXI	54 °C						

(1) *For JET A only, if TAT reaches -34 °C, monitor on FUEL SD page that fuel temperature remains higher than -36 °C.*

MINIMUM FUEL QUANTITY FOR TAKEOFF : 1 500 KG/3 307 LB

Applicable to: ALL

WING TK LO LVL warning must not be displayed on ECAM for takeoff.

WHEN USING JP 4 AND JET B

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Fuel in center tank is to be regarded as unusable if the wing fuel temperature exceeds the following values before engine start and if the given flight level is exceeded before the center tank fuel has been used:

- +30 °C not above FL 350
- +40 °C not above FL 300
- +49 °C not above FL 250

Reason At high altitude with high fuel temperature, the pressure delivered by the center tank pumps becomes lower than the pressure delivered by the wing tank pumps.

FUEL MANAGEMENT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- Tanks must be emptied in the following order:
  - center tank then wing tanks
- Takeoff on center tank is prohibited

FUEL MIXABILITY

Applicable to: ALL

The various types of fuel can be mixed in all proportions.
The freezing point of a fuel mixture varies, based on non-linear laws. If required, determine the fuel freezing point of the fuel mixture.

Brakes..... A
AUTOBRAKE..... B
TAXI WITH DEFLATED TIRES..... C
Nosewheel Steering (NWS)..... D

Intentionally left blank

BRAKES

Applicable to: ALL

Maximum brake temperature for takeoff (brake fans ◁ off)..... 300 °C

The braking system is not designed to hold the aircraft in a stationary position when a high thrust level is applied on at least one engine. During ground procedures that require a thrust increase with braking, the flight crew must ensure that the aircraft remains stationary.

AUTOBRAKE

Applicable to: ALL

Use of the autobrake does not relieve the pilot of his responsibility to safely stop within the available runway length, by taking over brake control with brake pedals, if necessary.

The flight crew can disengage the automatic braking system by:
- Pressing the pushbutton of the armed mode, or
- Applying sufficient pressure to the brake pedals.

TAXI WITH DEFLATED TIRES

Applicable to: ALL

If tire damage is suspected after landing or after a rejected takeoff, an inspection of the tires is required before taxi. If the tire is deflated but not damaged, the aircraft can be taxied at low speed with the following limitations :

1. If one tire is deflated on one or more gears (ie. a maximum of three tires), the speed should be limited to 7 kt when turning.
2. If two tires are deflated on the same main gear (the other main gear tires not being deflated), speed should be limited to 3 kt and the nose wheel steering angle limited to 30 °.

NOSEWHEEL STEERING (NWS)

Applicable to: ALL

The nosewheel steering angle is limited to 75 ° when using the handwheels.
For towing and pushback, the nosewheel steering angle is limited to 95 °.
Towbarless towing and pushback on the nose landing gear is approved for the "accepted towbarless towing vehicles" that are listed in the Airbus SIL 09-002, but the nosewheel steering angle must be limited to 85 °.

Inertial Reference System ..... A
Enhanced Ground Proximity Warning System (EGPWS) ◁ ..... B
ISIS C

Intentionally left blank

INERTIAL REFERENCE SYSTEM

Applicable to: B-HSQ, B-HSR

IRS ground alignment has been demonstrated to be satisfactory up to 73 ° latitude.

In NAV mode, the IRS will not provide a valid magnetic heading:

- For latitude greater than 73 ° North,
- For latitude greater than 60 ° South.

Flight outside the above-noted limits is prohibited.

INERTIAL REFERENCE SYSTEM

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

IRS ground alignment has been demonstrated to be satisfactory up to 82 ° latitude.

In NAV mode, the IRS will not provide a valid magnetic heading:

- For latitude greater than 82 ° North,
- For latitude greater than 73 ° North, between 90 ° and 120 ° West (magnetic polar region),
- For latitude greater than 60 ° South.

Flight outside the above-noted limits is prohibited.

ENHANCED GROUND PROXIMITY WARNING SYSTEM (EGPWS) ⋖

Applicable to: ALL

- Aircraft navigation is not to be predicated on the use of the terrain display.
  The terrain display is only intended as a situational awareness tool, and may not provide the accuracy on which to solely base terrain avoidance maneuvers.
- The EGPWS enhanced function should be inhibited (TERR pushbutton to OFF, on the GPWS panel) when the aircraft position is less than 15 nm from the airfield :
  - For operations to/from runways not incorporated in the EGPWS database.
  - For specific approach procedures, which have previously been identified as potentially producing false terrain alerts.

ISIS

Applicable to: B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

When both PFDs are lost, the ISIS bugs function must not be used.

OPERATING CONDITION	TIME LIMIT	EGT LIMIT	NOTE
TAKEOFF and GO-AROUND	5 min	635 °C	
	10 min		Only in case of engine failure
MCT	Unlimited	610 °C	
STARTING		635 °C	

OIL

Applicable to: ALL

OIL TEMPERATURE

Minimum prior to exceeding idle..... -10 °C
Minimum prior to takeoff..... 50 °C
Max continuous temperature..... 155 °C
Max transient temperature (15 min)..... 165 °C
Minimum starting temperature..... -40 °C
Minimum oil quantity..... (*Refer to PRO-NOR-SOP-04-Before Walk Around-ECAM.*)

MINIMUM OIL PRESSURE

Minimum oil pressure..... 60 PSI

RPM

Applicable to: ALL

N1 max..... 100 %

Note: *The N1 limit depends upon ambient conditions and engine airbleed configuration. These may limit N1 to a value lower than the one noted above (For additional information, refer to Performance/Thrust Ratings).*

N2 max..... 100 %

STARTER

Applicable to: ALL

- 3 consecutive cycles : 2 cycles of 2 min each, followed by a 3rd cycle of 1 min .
- Pause between start attempts : 15 s.
- Cooling period, following 3 start attempts or 4 min of continuous cranking : 30 min .
- No running engagement of the starter, when N2 is above 10 % on ground, and 18 % in flight.

REVERSE THRUST

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- It is not permitted to select reverse thrust in flight
- It is not permitted to back up the aircraft with reverse thrust
- Maximum reverse should not be used below 70 kt. (Idle reverse is permitted down to aircraft stop).

REVERSE THRUST

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- It is not permitted to select reverse thrust in flight.
- It is not permitted to back up the aircraft with reverse thrust.
- Maximum reverse should not be used below 70 kt (or when the airspeed indication starts to fluctuate). Idle reverse is permitted down to aircraft stop.

REDUCED THRUST TAKEOFF

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- Takeoff at reduced thrust is only permitted, if the airplane meets all applicable performance requirements at the planned takeoff weight, with the operating engines at the thrust available for the assumed temperature.
- Thrust reduction must not exceed 25 % of the full rated takeoff thrust. To meet this requirement, the flexible temperature must not be higher than ISA + 55 °C(T MAX FLEX).
- The assumed temperature must not be lower than the flat rating temperature, or the current OAT.
- Takeoff at reduced thrust is not permitted on contaminated runways.
- Takeoff at reduced thrust is permitted with any inoperative item affecting the performance, only if the associated performance shortfall has been applied to meet all performance requirements at the takeoff weight, with the operating engines at the thrust available for the flex temperature.

REDUCED THRUST TAKEOFF

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- Takeoff at reduced thrust is only permitted, if the airplane meets all applicable performance requirements at the planned takeoff weight, with the operating engines at the thrust available for the assumed temperature.
- Thrust reduction must not exceed 25 % of the full rated takeoff thrust. To meet this requirement, the flexible temperature must not be higher than ISA + 42 °C(T MAX FLEX).
- The assumed temperature must not be lower than the flat rating temperature, or the current OAT.
- Takeoff at reduced thrust is not permitted on contaminated runways.
- Takeoff at reduced thrust is permitted with any inoperative item affecting the performance, only if the associated performance shortfall has been applied to meet all performance requirements at the takeoff weight, with the operating engines at the thrust available for the flex temperature.

CROSS WIND OPERATION ON GROUND

Applicable to: ALL

This engine is capable of starting in crosswinds up to 35 kt .

GENERAL DESCRIPTION

Applicable to: ALL

An Operations Engineering Bulletin (OEB) is issued to rapidly inform operators of any deviations from initial design objectives that have a significant operational impact. An OEB provides the operators with technical information and temporary operational procedures that address these deviations.

TYPE OF OEB

OEBs can either be red or white, depending on their level of priority.

- RED OEBs are issued to indicate that non-compliance with the recommended procedures may have a significant impact on the safe operation of the aircraft.
- WHITE OEBs are issued to indicate that non-compliance with the recommended procedures may have a significant impact on aircraft operation.

Airbus strongly recommends that all Operators rapidly apply the OEB corrective actions as soon as they become available, particularly for red OEBs.

OEB CONTENT AND MANAGEMENT

An OEB:
- Is temporary and usually focuses on one operational subject only,
- Is included in the OEB section of both the FCOM and QRH. The procedural part of each white or red OEB (OEB PROC) is provided in the OEB section of the QRH, so that the flight crew can easily access the procedures,
- Remains applicable until the appropriate corrective actions are completed.

Note: After installation of the OEB corrective modification/Service Bulletins (SB): if an Operator reinstalls any spare equipment for which there was an associated OEB, it is Operator's responsibility to ensure that this OEB be applied again for the applicable aircraft.

OEB IN THE FCOM

The content of each OEB includes:
- The reason for issue,
- Technical explanations of the deviation from the initial design objectives,

- The operational impact if the flight crew does not apply the OEB procedure,

  The conditions for applying the OEB procedures :
  - ECAM warning/caution affected by the OEB,
  - Cockpit effects,
  - Flight phases,
  - Specific event.

- The OEB operational procedure(s) to be applied,
- The corrective actions that cancel the OEB (if available)
- The OEB REMINDER codes, (if applicable).

OEB IN THE QRH

Each FCOM OEB has an associated “OEB PROC”in the OEB section of the QRH, that includes:
- The title of the OEB PROC,
- The “ECAM ENTRY" field:
  This section identifies whether or not one of the possible conditions for applying the OEB PROC is an ECAM warning/caution.
  The flight crew must disregard the ECAM procedure and/or STATUS of the ECAM alerts listed in the "ECAM ENTRY" field and must apply the QRH’s OEB procedure instead.
- The OEB operational procedure(s) that the flight crew must apply.

LIST OF EFFECTIVE OEB

The List of Effective operation Engineering Bulletins(LEOEB) enables to review all the OEBs that are applicable to the fleet. Each time an Operations Engineering Bulletin (OEB) is issued or revised, the List of Effective Operations Engineering Bulletins (LEOEB) is updated.

M(1)	Identification	T(2)	E(3)	REV. Date	Title
	OEB38 issue 1	R	N	18 MAR 11	Erroneous Radio Altimeter Height Indication
	Criteria: SA Applicable to: ALL				

(1) Evolution code: N=New, R=Revised, E=Effectivity
(2) Type of OEB: R=Red, W=White
(3) Affects ECAM: Y=Yes, N=No

The LEOEB consists of:

The "M" field that may provide the following Evolution Code
- The "N" letter indicates a new OEB
- The "R" letter indicates a revised OEB
- The "E" letter indicates an aircraft validity change on the OEB

The "Identification" field which identifies the OEB with its identification number

Note: The FCOM OEB and associated QRH OEB PROC have the same OEB number in order to be consistent. However, the issue number of the QRH OEB PROC and the FCOM OEB may be different, because a revision of an FCOM OEB does not necessarily result in a revision of the corresponding QRH OEB PROC, that only provides the procedure part.

The "T" field indicates the Type of OEB:
- The "W" letter indicates a white OEB
- The "R" letter indicates a red OEB

Note: OEBs are listed by type of OEB (RED OEBs first, then WHITE OEBs), and in numerical order for each type of OEB. This enables the flight crew to easily review the OEBs before flight

The "E" field indicates whether or not the OEB affects ECAM procedure(s). This enable the flight crew to easily review the OEBs before flight particularly for Operators that use the OEB REMINDER function:
- The "Y" letter indicates that the OEB affects ECAM procedure(s)
- The "N" letter indicates that at least one of the procedures provided in the OEB does not affect ECAM procedure(s)

CAUTION	When Airbus provides the Operator with the LEOEB, the information "AFFECTS ECAM : Y" ("E" field) does not necessarily mean that: - The OEB only affects ECAM alerts: The flight crew must also check in the OEB whether or not they have to memorize some additional operational recommendations that are not related to ECAM alerts. - For Operators using the OEB REMINDER function, the Operator's maintenance personnel has activated the OEB REMINDER codes for this OEB onboard the aircraft. It is the Operator's responsibility to define a suitable process for providing the flight crew with confirmation that the OEB REMINDER codes are activated for the ECAM alerts affected by OEBs.

The "Rev Date" field indicates the date at which the OEB content was issued/ changed
The "Title" field provides the OEB title.

REVIEW OF THE OEB

In accordance with the Standard Operating Procedures, and before each flight, the flight crew must review all OEBs that are applicable to their aircraft. If the OEB conditions are applicable, the flight crew must apply the operational procedure(s) that is in the QRH OEB section.

DISTRIBUTION

OEB are distributed to all affected Operators. The Operators shall provide flight crews with the content of the OEB without delay.

OEB REMINDER FUNCTION

The OEB reminder function provides operational help to the flight crew by enabling them to clearly identify on the ECAM all procedures and STATUS messages superseded by an OEB procedure. When a situation causes an ECAM warning/caution to trigger, a message informs the flight crew in real time that there is an OEB for the displayed ECAM warning/caution and/or STATUS, and as a result, that the ECAM procedure and/or STATUS is not applicable. In this case, a specific ECAM message informs the flight crew to refer to the QRH. For more information *Refer to DSC-31-27 General*.

OEB REMINDER CODE

The maintenance personnel must enter specific OEB REMINDER code(s) in the FWC OEB database in order to update the ECAM.
These OEB REMINDER codes are provided in the FCOM OEB chapter only, and are sent to the Operator's Flignt Operations department along with the associated QRH OEB PROC. This is to ensure that the OEB database is not updated before the OEB procedure is available in the QRH and FCOM onboard documentation.

Good coordination between the Airline's/Operator's Flight Operations department and the Airline's/Operator's Engineering department must be established, in order to:

- Ensure that the QRH OEB section is updated onboard the aircraft before the activation of the OEB REMINDER function for a specific OEB.
- Rapidly send information about the OEB REMINDER codes to the Engineering department for a rapid update of the ECAM.
- Provide the flight crew with confirmation that the OEB REMINDER codes are activated onboard the aircraft for the ECAM alerts affected by OEBs.

CAUTION	As soon as the maintenance personnel has embodied the corrective action that cancels the OEB PROC on a specific aircraft, the Operator must ensure that: 1. Maintenance personnel has deactivated the OEB REMINDER function for the specific OEB, before informing their Flight Operations department of the installation of the OEB correction action. 2. The QRH OEB section onboard the aircraft is updated to remove the specific OEB from the applicable aircraft.

CROSS REFERENCE BETWEEN THE FORMER AND NEW OEB IDENTIFICATIONS

Applicable to: ALL

Following the entry into service of the new digital FCOM/QRH, the OEB/OEBPROC identifications were changed.

Note: The former OEB identification is also provided within each OEB.

The following table provides the cross reference between the former and the new OEB/OEBPROC identifications:

Aircraft	Manual	Former OEB Identification	Issue	New OEB Identification	OEB Type	OEB Title
A318/319/320/321	FCOM	78	6	OEB 2	R	Braking Misbehaviour

OEB11 Issue 1.0
Associated with QRH OEB Proc N°: OEB11/1.0
"ENG 1(2) OIL FILTER CLOG" ECAM CAUTION DURING FLIGHT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue: This OEB replaces the A320 OEB 152.
Engine bearing N°3 failure cases, leading to in-flight shutdowns and, in some cases, accompanied by oil door/smoke in the cabin/cockpit, have been reported on V2500-A5 engines. In a recent case, where a N°3 bearing failure is highly suspected, significant smoke entered the cabin and cockpit, leading the crew to deploy the oxygen masks and divert. In most of these events, an ENG 1(2) OIL FILTER CLOG ECAM caution was displayed prior to the in-flight shutdown.

Applicable to: All A320 family aircraft fitted V2500-A5 engines.

Cancelled by: MOD 35795 (SB A320 72-1029).

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

	OEB-11		**"ENG 1(2) OIL FILTER CLOG" ECAM Caution During Flight**	00013200.0001001	30 MAR 12
	Criteria: V2500-A5 **Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI**				

"ENG 1(2) OIL FILTER CLOG" ECAM CAUTION DURING FLIGHT

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

EXPLANATION

These events are the consequence of a quality issue concerning the HPC stubshaft coating on a specific batch of engines. Only V2500-A5 engines in the serial number range V10600 to V11365 with bearing Part Number 2A1165 are affected.

In service reports have shown that the ENG 1(2) OIL FILTER CLOG ECAM caution is frequently a symptom of engine bearing damage, that could potentially lead to smoke entering the cabin via the pack of the affected side.

In some cases, this ECAM caution could be accompanied by a variation in oil pressure, an increase in engine vibrations, and/or engine stall/surge.

A N°3 bearing failure can potentially result in damage to the carbon seal at the exit of the bearing chamber, thus causing some oil to migrate to the HP compressor and, subsequently, to contaminate the aircraft's air conditioning system. This could lead to oil odor/smoke in the cabin and the cockpit.

PROCEDURE

The ECAM does not request any pilot action, in the event of an ENG 1(2) OIL FILTER CLOG ECAM caution.

However, to minimize the risk of contaminating the air conditioning system by oil fumes: while continuing normal engine operation, systematically apply the following procedure, in any case where the ENG 1(2) OIL FILTER CLOG ECAM caution occurs in flight:

ENG BLEED (affected side).....OFF

Prevents possible bleed contamination by engine oil.

PACK (affected side).....OFF

Switching OFF one pack enables the remaining pack to operate at 120 %, without any risk of misbehavior on the remaining bleed. Keep the pack on (affected side), in case of an MEL dispatch with the other pack inoperative.

The pack that has been switched off remains available, with the crossbleed valve open. Therefore, switch it on, in case of a subsequent independent malfunction affecting the operating pack.

X BLEED..... OPEN

Opening the crossbleed valve enables the wing anti-ice to be used, when needed.

CLOSELY MONITOR ENGINE PARAMETERS for surge / stall, oil pressure variations, abnormal engine vibrations and, when necessary, apply the associated procedure.

Continued on the following page

"ENG 1(2) OIL FILTER CLOG" ECAM CAUTION DURING FLIGHT (Cont'd)

- **If, after the oil filter clog indication, the engine experiences or has already experienced a surge/stall (audible surge detected/undetected by the ECAM) possibly accompanied by a yaw effect on the aircraft:**
  ENG (affected) THRUST LEVER..... IDLE
  Reducing the thrust of the affected engine minimizes further damage to the engine's rotary machinery, but will not necessarily prevent more oil from entering the gas path. Maintain engine at idle, and consider engine shutdown, when high vibration occurs, or oil quantity/oil pressure drops low.

Note: ENG 1(2) OIL FILTER CLOG ECAM caution occurring on ground during engine start are frequently due to low oil viscosity and may be self-recoverable: No maintenance action is required, if the message appears before the engine has reached a stabilized idle condition (Refer to FCOM "ENG 1(2) OIL FILTER CLOG" procedure). Maintenance action is required, if it does not disappear when the engine is stabilized at idle.

OEB REMINDER

For aircraft that have the OEB Reminder Function activated, the ENG 1 OIL FILTER CLOG ECAM caution procedure and status may be flagged.
If the ENG 1 OIL FILTER CLOG ECAM caution procedure is flagged, the ECAM will display the "REFER TO QRH PROC"line or "REFER TO QRH/OEB PROC"line (depending on Flight Warning Computer (FWC) standard) instead of the procedure itself.
To flag the procedure and the status that corresponds to the ENG 1 OIL FILTER CLOG ECAM caution, the following code must be entered in the FWC OEB database:

CODE	WARN	STS
ENG 1 OIL FILTER CLOG 77/00/056/109	Y	N
ENG 2 OIL FILTER CLOG 77/00/057/110	Y	N

CORRECTIVE ACTION

The embodiment of the Airbus SB A320 72-1029 cancels the need for this OEB.
For the aircraft that are affected by the above mentioned batch of engines, the IAE SB No. V2500 ENG-72-0459 must be embodied first before reporting to Airbus the embodiment of Airbus SB A320 72-1029.
For the aircraft that are not affected by the above-mentioned batch of engines, Operators must also send the SB A320 72-1029 reporting sheet to Airbus.

DUAL FM RESET UPON RADIAL FIX INFO ENTRY

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue: This OEB replace the A320 OEB 169
Several Operators reported that both FMS reset immediately after the flight crew inserted a FIX INFO radial that intercepted the F-PLN just prior to the last point of the approach (Missed Approach Point (MAP), or runway threshold).
Therefore, this OEB is issued to provide the operational recommendations that should be applied, in order to help prevent this situation.

Applicable to: All A318/A319/A320/A321 aircraft with FMS2 Pegasus :

- P1C8 MOD 31896, or
- P1C9 MOD 32222, or
- P1C11 MOD 34573, or
- P1I8 MOD 31897.

Cancelled by: FMGC with PEGASUS H2 - Release 1A

- H2C12 MOD 38778, or
- H2I11 MOD 38779.

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

OPERATIONS ENGINEERING BULLETINS

DUAL FM RESET UPON RADIAL FIX INFO ENTRY

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

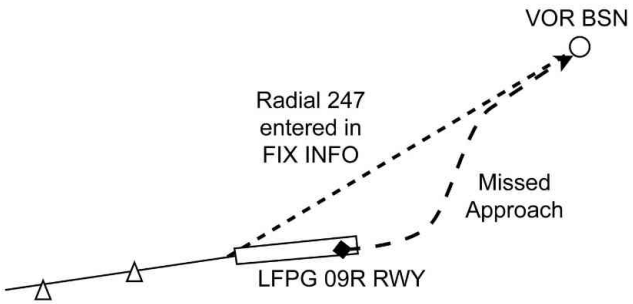
DUAL FM RESET UPON RADIAL FIX INFO ENTRY

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTG, B-HTH, B-HTI

EXPLANATION

The diagram below illustrates one of the reported events that occurred during the aircraft's approach into Paris CDG airport RWY 09R, after inserting the BSN VOR 247 ° radial in the MCDU FIX INFO page.

Paris CDG diagram



Paris CDG diagram

In some reset cases, the FM lost the GW/CG information. When the GW/CG were re-inserted, the FM reset again. However, F-PLN data were not lost, and the AP/FD/ATHR remain engaged.
In other reset cases, the FM lost the F-PLN and all other manually-entered data.
Airbus has reproduced the reported scenarios in the simulator. Investigations indicate that the FMS cannot perform the associated prediction computations, when FIX INFO radials intersect the F-PLN just before the last point of the approach. These specific conditions systematically cause the FM reset.
The reset may occur during any flight phase, as soon as the corresponding FIX INFO radial is inserted, and the associated predictions are computed.

Continued on the following page

DUAL FM RESET UPON RADIAL FIX INFO ENTRY (Cont'd)

Due to the fact that several FM resets may occur consecutively, it may take some time for the FMS to automatically recover.

PROCEDURE

PREVENTIVE PROCEDURE

Do not use the FIX INFO function with any radials that could intercept the F-PLN just before the last point of the approach (less than 0.1 nm).

Note: The last point of the approach corresponds to the runway threshold for an ILS approach, or to the Missed Approach Point (MAP) for a Non-Precision Approach (NPA).

RECOVERY PROCEDURE

If disengaged, consider reengagement of the AP/FD and ATHR.
While the FMS is recovering, consider using RMP backup tuning for navigation.

- **If the F-PLN is not lost:**

  Normal FMS operation can be recovered by clearing the radial FIX INFO, and then by re-entering the GW/CG.

- **If the F-PLN is lost:**

  When the FMS has automatically recovered, perform the associated procedures (*Refer to QRH/ABN-22 LOSS OF FMS DATA IN DESCENT/APPROACH (Severe Reset)*).

CORRECTIVE ACTION

This OEB is cancelled by PEGASUS H2-R1A FMS standard.

NO LOCALIZER OR GLIDE SLOPE CAPTURE IN APPROACH

Applicable to: B-HSJ, B-HSL, B-HTD

EXPLANATION

Investigations have indicated that the LOC* capture mode did not engage due to an automatic, internal reset of one Multi-Mode Receiver (MMR). This automatic reset causes the LOC and/or G/S deviation data computed by this MMR to continuously change from Normal Operation to No Computed Data, approximately every second. This can only be stopped, on ground, if the maintenance crew cuts the MMR power for more than 10 s.

The Master FMGC must receive a valid LOC signal from its onside MMR for a minimum of 3 s to enable LOC* mode engagement. When the MMR associated to the Master FMGC periodically resets, the associated LOC signal is valid for less than one second, which explains why the LOC* mode does not engage.

In such cases, when the AP and/or FD is engaged and the LOC and G/S modes are armed, the aircraft may unexpectedly fly through the ILS beam without capturing it. The ILS identification and deviation symbols displayed on the PFD (and on the ND in ROSE-LS mode) may intermittently disappear. However, when displayed, these ILS deviation symbols are reliable.

The possibility of both MMRs being simultaneously affected is very remote. Therefore, it is highly probable that the second MMR is operative and will continue to provide constant and valid data to the Slave FMGC.

If the flight crew changes the AP in command, the Slave FMGC becomes Master, and will use the associated, valid data from its onside MMR. This will enable the localizer and/or the glide slope capture modes to engage.

Note: *1. If both APs are engaged, FMGC1 is Master. To change the Master FMGC from FMGC1 to FMGC2, the flight crew must disengage AP1 pb by pressing the AP1 pb on the FCU.*

2. If the autopilot is disengaged, and both FDs are engaged, FMGC1 is Master by default. It is possible to change the Master FMGC from FMGC1 to FMGC2, by engaging AP2, or disengaging FD1.

PROCEDURE

In accordance with the FCOM Standard Operating Procedures (*Refer to PRO-NOR-SOP-18 Precision Approach Pattern*), the flight crew should closely monitor the localizer and glide slope capture, for every ILS approach.

- **If LOC* mode does not engage when expected, the flight crew should:**

  Perform the ILS interception using the LOC raw data deviations. The FD and AP can be used in selected modes (HDG-V/S modes, or preferably TRK-FPA modes) for this purpose.

Continued on the following page

NO LOCALIZER OR GLIDE SLOPE CAPTURE IN APPROACH (Cont'd)

Consider changing the Master FMGC:

- **If the AP is engaged:**

  Change the AP in command

  (If AP1+2 are engaged, change to AP2, by pressing the AP1 pb on the FCU to disengage AP1)

- **If the AP is disengaged, and the FDs are engaged:**

  Turn off FD1

Then, attempt to reengage the LOC and G/S modes, by pressing the APPR pb.

LOC* (G/S*) mode should engage as expected, and the ILS can then be flown in LOC and G/S modes. However, the flight crew should disregard the approach capability on the FMA, and perform only a CAT I approach with a manual landing.

Note: *If it is still not possible to intercept the ILS after changing the Master FMGC, the flight crew must perform an ILS approach using raw data. The AP/FD can be used in selected modes (HDG/VS, or preferably TRK/FPA). The flight crew should disarm the APPR (LOC) mode(s) by setting the APPR (LOC) pb to OFF on the FCU, and then perform a CAT I approach with a manual landing.*

CORRECTIVE ACTION

This OEB is cancelled by the installation of the MMR P/N 822-1152-122.

NO SRS ENGAGEMENT DURING GO AROUND BELOW MDA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue: This OEB replaces the A320 OEB 188.
One Operator reported a case where the flight crew initiated a Go Around slightly below the Minimum Descent Altitude (MDA), and the aircraft did not pitch up as expected. The flight crew performed a non precision approach (a VORDME approach) using the FINAL APP managed guidance mode with the AP1 (Autopilot) engaged during the final approach.
This OEB is issued to provide flight crews with an operational procedure to avoid such aircraft behavior.
The operational procedure provided in this OEB applies to all Non Precision Approaches, for both conventional approaches and RNAV approaches, flown in FINAL APP managed guidance mode.

Applicable to: All A318/A319/A320/A321 aircraft

Cancelled by: Flight Guidance (FG) "I11" standard part of FMGC S4I11 (MOD 37252), P1I11 (MOD 37311) or FG "C12" standard part of FMGC S4C12 (MOD 37935), P1C12 (MOD 37934).

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

NO SRS ENGAGEMENT DURING GO AROUND BELOW MDA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HTD, B-HTE, B-HTF

EXPLANATION

Note: The following behavior does not occur when the flight crew uses lateral managed guidance only (NAV-FPA or NAV-V/S).

The following occurs when the flight crew uses the FINAL APP managed guidance mode, and engages either AP1 or FD1 (AP OFF, FMGC1 is the master):
During a non-precision approach, when the aircraft is reaching MDA (MDH) minus 50 ft, or the Missed Approach Point (MAP), the FMGC automatically commands an AP/FD disconnection, in order to automatically disengage the FINAL APP managed guidance mode. After the AP/FD disconnection, the FD engages again, either in heading-vertical speed (HDG-V/S), or track-Flight Path Angle (TRK-FPA) mode, with the current aircraft targets.
If the flight crew initiates a go-around below MDA (MDH) during a short period of time (approximately 600 ms) after the AP/FD disconnection, no FMGC takes over to engage the go-around guidance modes, as expected. This is due to the fact that both FMGCs are not entirely synchronized when the AP/FD automatically disconnects.
As a result, the GA TRK lateral guidance mode and the SRS vertical guidance mode do not engage during the go-around. In addition, the FD remains in a basic guidance mode (i.e. HDG-V/S or TRK-FPA), and provides the flight crew with pitch down orders that are not appropriate.
Investigation has demonstrated that if the flight crew disengages the FINAL APP managed guidance mode during the final stage of the approach, the SRS and the GA TRK guidance modes engage as expected, when the flight crew initiates a go-around slightly below MDA(MDH).

PROCEDURE

During a non precision approach, when using the FINAL APP managed guidance mode:

- **At DA(DH) or MDA(MDH), or earlier in approach if visual conditions are obtained:**
  DISENGAGE the FINAL APP mode by pressing the APPR pushbutton on the FCU.

When the flight crew presses the APPR pb in order to disengage the FINAL APP managed guidance mode, a basic vertical guidance mode, either V/S or FPA, engages.

This ensures that the SRS and GA TRK guidance modes correctly engage, if the flight crew initiates a go-around slightly below MDA (MDH).

Continued on the following page

NO SRS ENGAGEMENT DURING GO AROUND BELOW MDA (Cont'd)

CORRECTIVE ACTION

This OEB is cancelled by the installation of the Flight Guidance (FG) "I11" standard part of FMGC S4I11 (MOD 37252), P1I11 (MOD 37311) or FG "C12" standard part of FMGC S4C12 (MOD 37935), P1C12 (MOD 37934).

ERRONEOUS VERTICAL PROFILE DURING RNAV, LOC AND LOC B/C APPROACHES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue:

This OEB replaces the A320 OEB 189.

This OEB is issued to provide Operators with the operational recommendations to apply in cases where the flight crew performs an RNAV or a LOC or LOC Back Course (B/C) approach with the MAP located before the runway (RWY) threshold.

This is because in such cases, the FMGC does not compute the vertical flight path correctly. As a result, it may cause the aircraft, when flown in managed vertical guidance, during an RNAV approach, to fly a vertical flight path lower than the published one on the approach procedure chart.

This anomaly also applies to the vertical deviation indication symbol, VDEV.

These recommendations were originally published in *Refer to FCOM Standard Operating Procedure - Non Precision Approach section*. Due to the fact that more and more RNAV procedures are being published in the Instrument Approach Procedures (IAP), Airbus found it necessary to publish this OEB in order to highlight these recommendations.

Applicable to:

All A320 family aircraft fitted with the Honeywell FMS.

Cancelled by:

Honeywell FMS2 "Release 1A" Standard (MOD 38778 on CFM aircraft, or MOD 38779 on IAE/PW aircraft), or a future standard for legacy FMS (Mod TBD).

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this

OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

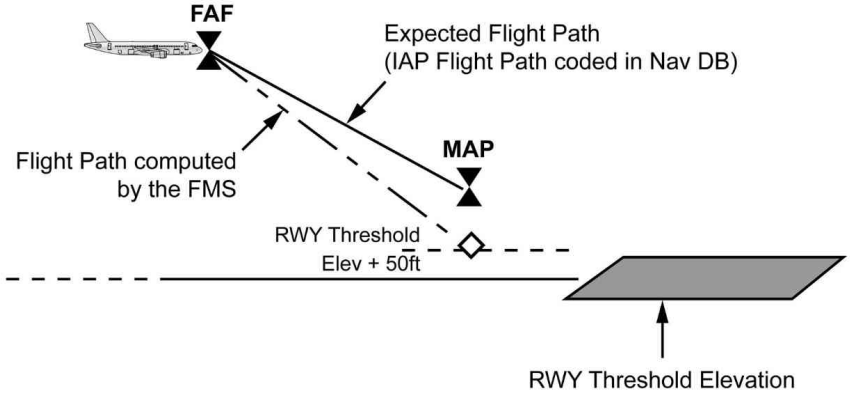
ERRONEOUS VERTICAL PROFILE DURING RNAV, LOC AND LOC B/C APPROACHES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

EXPLANATION

When the FMGC identifies an IAP that is labelled as RNAV in the navigation database, and that is labelled as RNV on the MCDU, it builds the final approach vertical flight path assuming that there is an altitude constraint at the MAP equal to the runway threshold elevation plus 50 ft.
As a result, when the MAP is located before the runway (RWY) threshold, the FMGC computes an erroneous vertical flight path for the final approach, an erroneous crossing altitude at the MAP, and displays an erroneous vertical deviation indication (VDEV symbol) on the PFD, when flying the approach. This VDEV anomaly also applies to the LOC and LOC B/C approaches with the MAP located before the runway (RWY) threshold.



MAP: Missed Approach Point
FAF: Final Approach Fix

Therefore, for RNAV approaches, when the MAP is located before the runway threshold, the flight crew cannot use flight guidance in FINAL APP mode, and they must disregard the VDEV symbol.
The flight crew must fly the LOC and LOC B/C approaches in selected vertical guidance mode (FPA or V/S mode), and they must disregard the vertical deviation symbol (VDEV).

Continued on the following page

ERRONEOUS VERTICAL PROFILE DURING RNAV, LOC AND LOC B/C APPROACHES (Cont'd)

Note that approaches labelled as "GPS"on the MCDU are not affected and can be flown in FINAL APP mode regardless of the MAP position.

PROCEDURE

FOR RNAV APPROACHES

For any approach labelled as RNV on MCDU:

VERIFY on the approach chart and on the MCDU that the MAP is at the runway threshold
On the MCDU F-PLN page, if the last waypoint of the active F-PLN, displayed in green, is identified as a runway (e.g. LFB032L), it means that the runway threshold is the MAP.

- **If the MAP is located at the runway (RWY) threshold:**
  Use of the vertical managed guidance mode (FINAL APP) is possible

- **If the MAP is not located at the runway (RWY) threshold:**
  DO NOT USE vertical managed guidance (FINAL APP)
  USE NAV mode for lateral guidance
  USE SELECTED vertical guidance mode only (FPA is recommended)
  DISREGARD the VDEV symbol, and crosscheck the final descent using altitude versus distance to the MAP.

Note: Approaches labelled as "GPS"on the MCDU can be flown in FINAL APP mode, regardless of the MAP position.

FOR LOC, OR LOC BACK COURSE (B/C) APPROACHES

CHECK the position of the MAP on the approach chart

- **If the MAP is located at the runway (RWY) threshold:**
  VDEV symbol can be used to assist the flight crew in flying the vertical flight path in selected mode.

- **If the MAP is located before the runway (RWY) threshold:**
  DISREGARD the VDEV symbol, and crosscheck the final descent using the altitude versus the distance to the MAP.

	OEB-36		**No SRS Engagement During Go Around in the Case of EPR Mode Fault**	00013568.0003001	30 MAR 12
	Criteria: 22-1203, IAE, P8015, P8486, P9126 **Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI**				

NO SRS ENGAGEMENT DURING GO AROUND IN THE CASE OF EPR MODE FAULT

Applicable to: B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR, B-HTG, B-HTH, B-HTI

EXPLANATION

The following occurs in case of go-around when engines are in N1 control mode (EPR control mode inoperative).
If the flight crew initiates a go-around, go-around modes do not engage and the FMS does not engage the GO AROUND phase, as expected. The Flight Director (FD) does not engage in go-around mode but either remains in current mode or reverts in basic guidance mode (i.e. V/S-HDG or FPA-TRK).
Consequently FD crossbars provide the flight crew with inappropriate pitch down orders.
If the FD is OFF (or the Flight Path Vector is used) the FD crossbars will not automatically engage (even with the automatic FD crossbars engagement during go-around).
If initially engaged, Auto Pilot(s) (APs) disengages.
As a consequence the flight crew will have to perform a manual go-around and simultaneously to disengage the FD (if previously engaged). Afterwards APs and FDs can be reengaged.
The landing capability is limited to CAT 1.

PROCEDURE

In the case of go-around with EPR control mode inoperative, perform a manual go-around with no FD:

Maximum landing capability is CAT 1.

Note: To perform a manual go-around with no FD, the PF simultaneously announces her/his intention, disengages the AP, applies TOGA and initiates the rotation.

GO-AROUND..... ANNOUNCE
AP (if engaged)..... OFF
BOTH FDs (if engaged)..... OFF

Action performed by the PNF on PF request.

THRUST LEVERS.....TOGA
ROTATION.....15 °OF PITCH

Rotate to 12.5 ° in case of engine failure.

FLAPS.....RETRACT ONE STEP
POSITIVE CLIMB.....ANNOUNCE
LDG GEAR UP.....ORDER
LDG GEAR.....SELECT UP
Adjust pitch to maintain VAPP

Continued on the following page

NO SRS ENGAGEMENT DURING GO AROUND IN THE CASE OF EPR MODE FAULT (Cont'd)

- **When appropriate:**
  Set both FDs to ON (basic guidance modes engage)
  Engage OP CLB and select appropriate speed and lateral mode
  AP use as required
- **When reaching thrust reduction altitude:**
  Set both thrust levers to CL detent
- **When reaching acceleration altitude:**
  Resume normal acceleration and climb procedures.

Note: CLB or LVR CLB will not flash on the FMA as the A/THR is not available. The FMS does not engage the GO AROUND phase.

OEB REMINDER

For aircraft that have the OEB reminder function activated, the ENG 1(2) EPR MODE FAULT ECAM caution procedure and status may be flagged.
If the ENG 1(2) EPR MODE FAULT ECAM caution procedure is flagged, the ECAM will display the FOR STS REFER TO QRH line or FOR STS REFER TO OEB line (depending on Flight Warning Computer (FWC) standard) instead of the status itself.
To flag the procedure and the status that corresponds to the ENG 1(2) EPR MODE FAULT ECAM caution, the following code must be entered in the FWC OEB database:

CODE	WARN	STS
ENG 1 EPR MODE FAULT 77/11/186/126	N	Y
ENG 2 EPR MODE FAULT 77/11/187/127	N	Y

CORRECTIVE ACTION

The embodiment of the following FG standard cancels the need for this OEB.

- Flight Guidance (FG) "I11A"
  - Thales/GE, MOD 151693, Airbus SB A320 22-1345, or
  - Honeywell, MOD 151692, Airbus SB: TBD
- "I12" standard (Mod/Airbus SB: TBD)

OEB38 Issue 1.0
Associated with QRH OEB Proc N°: OEB38/1.0
ERRONEOUS RADIO ALTIMETER HEIGHT INDICATION

Applicable to: ALL

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the safe operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is strongly recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they are available.

Reason for issue: This OEB replaces the A320 OEB 201
In follow-up to questions received from several Operators, the objective of this OEB is to remind Operators of the possible operational consequences of an erroneous Radio Altimeter (RA) height indication:

In addition this OEB is issued to:
- Highlight that during ILS (or MLS, GLS) approach with AP engaged, in the event of an unexpected early THR IDLE and FLARE modes engagement, the flight crew must immediately react to prevent the angle-of-attack from increasing.
- Provide explanation of erroneous RA height indication effects on Auto Flight System (AFS) and flight control law.

Applicable to: All A318/A319/A320/A321 operators
Cancelled by: TBD

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

RED OEB – RED OEB – RED OEB – RED OEB – RED OEB – RED OEB

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

RED OEB – RED OEB – RED OEB – RED OEB – RED OEB – RED OEB

M	Localization	T	DU Title	DU identification	DU date
	OEB-38		**Erroneous Radio Altimeter Height Indication**	00013580.0001001	30 MAR 12
	Criteria: SA **Applicable to: ALL**				
	OEB-38		**Erroneous Radio Altimeter Height Indication**	00013582.0001001	30 MAR 12
	Criteria: SA **Applicable to: ALL**				

ERRONEOUS RADIO ALTIMETER HEIGHT INDICATION

Applicable to: ALL

EXPLANATION

If an RA transmits erroneous height indication, this may have any of the following effects on aircraft systems depending on the flight phase. However, these effects may not necessarily occur in every case of an erroneous RA height indication.

On the Primary Flight Display (PFD):
- The RA height indication (possibly negative) is frozen and appears in either amber or green depending on the height
- Discrepancy between both PFDs (RA indications, FD orders, and if both AP engaged, PFD FMAs)

On the System Display (SD):
- A pulsing Cabin Differential Pressure Advisory appears on CAB PRESS page (No consequence on cabin pressure)

Warnings / Callouts:
- Untimely Terrain Awareness and Warning System (TAWS) alerts
- Untimely or absence of “RETARD”callout
- Untimely L/G GEAR NOT DOWN ECAM warning
- Absence or interruption of RA automatic callout (height announcement)
- Activation of AUTOLAND light warning light in ILS (or MLS, GLS) approach (Refer to FCOM DSC 22_30 - Auto Flight - Flight Guidance) with AP engaged in LAND or FLARE mode when:
  - One RA height goes below 200 ft and
  - The difference between both RA height indications is greater than 15 ft.

  Note: There is no ECAM message or audio warning in association to the AUTOLAND warning light. The AUTOLAND warning can be triggered even if AUTOLAND is not planned.

Auto Flight System mode changes (indicated on FMA):
- NAV mode engagement not possible after take off
- During an ILS (or MLS, GLS) approach, and depending on the engaged Flight Guidance (FG) modes, the consequences may be:

Continued on the following page

ERRONEOUS RADIO ALTIMETER HEIGHT INDICATION (Cont'd)

- Untimely/early engagement of the LAND / FLARE / THR IDLE modes if the RA height used by the FG is erroneous and lower than the real height.

  Note: *During ILS (or MLS, GLS) approach with AP and A/THR engaged, THR IDLE (RETARD) mode untimely engagement will be associated with an initial pitch attitude increase due to FLARE mode engagement.*

- In AUTOLAND, the LAND / FLARE / THR IDLE modes will not engage, if the RA height used by the FG is erroneous and higher than the real height.
- In case of Go-Around and if the RA is still frozen at a very low height indication:
  - SRS and GA TRK modes engage
  - NAV, HDG or TRK lateral modes cannot be selected
  - LVR CLB will not be displayed on the FMA at THR RED ALT
  - ALT* and ALT will not engage at FCU altitude.

  Disconnecting AP and resetting both FDs enable to recover basic mode (HDG and V/S).

During an ILS (or MLS, GLS) approach with AP engaged, if an erroneous and very low RA height indication occurs, THR IDLE and FLARE modes may engage early with the following consequences:

- In CONF FULL, the High Angle of Attack protection is not available. As a consequence the autopilot will not automatically disconnect at α prot +1 °. If the flight crew does not immediately react, the angle-of-attack will increase and may reach the stall value.
- In configurations other than CONF FULL, the High Angle of Attack autopilot disconnection is available. The autopilot will automatically disconnect at α prot +1 °.
- Loss of ALPHA FLOOR.
- The LOW ENERGY AUDIO WARNING – “SPEED SPEED SPEED”- remains available. In case of activation of LOW ENERGY AUDIO WARNING, the flight crew must react as per procedure (QRH ABN 22.2).
- In CONF FULL, the auto-trim function is inhibited.
- In manual flight or after AP disconnection, significant longitudinal sidestick input may be required.

PROCEDURE

During all phases of flight, the flight crew must monitor and crosscheck all primary flight parameters and FMA indications.

Continued on the following page

ERRONEOUS RADIO ALTIMETER HEIGHT INDICATION (Cont'd)

During ILS (or MLS, GLS) approach with AP engaged, in the event of an unexpected early THR IDLE and FLARE modes engagement, the flight crew must immediately react as follows:

- **Immediately** perform an automatic Go-Around (Thrust Levers set to TOGA),
  OR
- **Immediately** disconnect the AP,
  - Then continue the landing using raw data or visual references (FDs set to OFF),
    OR
  - Perform a manual Go-Around (Thrust Levers set to TOGA). Significant longitudinal sidestick input may be required.

Note: *1. If the flight crew does not immediately react, the angle-of-attack will increase and may reach the stall value.*

2. In case of Go-Around and if the RA is still frozen at a very low height indication:

- *SRS and GA TRK modes engage*
- *NAV, HDG or TRK lateral modes cannot be selected*
- *LVR CLB will not be displayed on the FMA at THR RED ALT*
- *ALT* and ALT will not engage at FCU altitude*

Disconnecting AP and resetting both FDs enable to recover basic modes (HDG and V/S).

3. In CONF FULL, the auto-trim function is inhibited. Retracting one step enable to recover the auto-trim function.

For all the others events that may occur during approach, there is no change in the procedures or in the recommended flight crew reactions.
Flight crews must report, in the technical logbook, any of the above-listed consequences of erroneous RA height.

CORRECTIVE ACTION

Airbus is currently investigating to find the permanent fixes that will cancel the need for this OEB.

AIR ENG 1(2) BLEED ABNORMAL PR OR AIR ENG 1(2) BLEED FAULT

Applicable to: ALL

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue: This OEB replaces the A320 OEB 203.
Subsequent to several dual bleed loss cases reported by Operators, Airbus decided to develop different technical solutions to improve the robustness of the bleed system. These technical solutions, although significantly reducing the number of dual bleed loss occurrences, cannot fully avoid such occurrences.
Therefore, this OEB is published in order to provide all SA Operators with operational procedures aiming at further reducing the number of dual bleed loss occurrences, whatever the bleed system solution installed.

Applicable to: All A320 family aircraft.

Cancelled by: FWC Standard H2-F6 (MOD 151269)

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

AIR ENG 1(2) BLEED ABNORMAL PR OR AIR ENG 1(2) BLEED FAULT

Applicable to: ALL

EXPLANATION

In case of AIR ENG 1(2) BLEED ABNORMAL PR or AIR ENG 1(2) BLEED FAULT ECAM cautions, the current associated ECAM procedures, ask to open the crossbleed valve in order to supply both Packs (or one Pack and the Wing Anti-Ice system) with the remaining engine bleed. This leads to an increase in air demand on the remaining engine bleed. On ageing bleed equipment or due to undetected failure, the remaining bleed may not succeed in sustaining this increase in air demand. In that case, it can result in an overheat of the remaining engine bleed and subsequent loss of the entire engine bleed system, leading to possible emergency descents. The purpose of this OEB is, therefore, to prevent from the loss of the remaining engine bleed by reducing the bleed air demand, when the first engine bleed has been already lost.

PROCEDURE

Apply the corresponding procedures if one of the following ECAM caution is triggered:

- AIR ENG 1(2) BLEED ABNORMAL PR
- AIR ENG 1(2) BLEED FAULT

AIR ENG 1(2) BLEED ABNORMAL PR

F/CTL SPOILER FAULT

Applicable to: ALL

EXPLANATION

Investigations have shown that the root cause of these events is the deterioration of an O-ring seal in the spoiler's servo-valve. This deterioration allows high hydraulic pressure to go in the extension piston chamber leading to an uncontrolled spoiler deflection in full position.
In most of cases, the autopilot has not enough authority to counteract the roll induced by spoiler runaway. Therefore, the autopilot disconnects and the flight crew takes over to recover wing level in normal law.
When this issue occurs, the F/CTL SPLR FAULT ECAM caution triggers and the F/CTL S/D page shows an amber deflected arrow on the failed spoiler. This information does not, however, enable the flight crew to determine whether the faulty spoiler is partially or fully deflected.
AIRBUS recommendations assume that if the F/CTL SPLR FAULT ECAM caution triggers, along with at least one amber deflected spoiler arrow displayed on the F/CTL S/D page, the spoiler is supposed to be fully deflected.

PROCEDURE

- **If F/CTL SPLR FAULT is triggered**

  F/CTL S/D page..... CHECK

  The flight crew should check the spoiler position on the F/CTL System Display page.

  - **If all amber spoilers are indicated retracted:**

    Loss of one or more spoilers in the retracted position. In such a case, the flight crew must apply the following operational procedure that reflects the F/CTL SPLR FAULT ECAM caution.

	Criteria: SA **Applicable to: ALL**				

L/G GEAR NOT DOWNLOCKED

Applicable to: ALL

EXPLANATION

The current L/G GEAR NOT DOWNLOCKED ECAM warning procedure requires the recycling of the landing gear before initiating L/G gravity extension.
Recent study has shown that waiting for 2 min after the recycling of the landing gear may allow gears to extend under normal powered extension. Waiting for 2 min before extending the landing gear by gravity will allow hydraulic pressure to continue to act on doors and gears.
In the case the landing gear is not locked down within 30 s after the lever is selected down, this waiting time may allow the normal landing gear extension to work successfully.
Therefore this OEB is issued to recommend that after the recycling of the landing gear, the flight crew waits for 2 min before extending the landing gear by gravity.

PROCEDURE

Apply the following procedure if the ECAM triggers the L/G GEAR NOT DOWNLOCKED warning:

L/G GEAR NOT DOWNLOCKED

This warning appears, if the landing gear sequence is not completed after 30 seconds.

L/G lever..... RECYCLE

•IF GEAR NOT DOWNLOCKED AFTER 2 MINUTES:

L/G GRAVITY EXTENSION PROC..... APPLY

STATUS

The status displayed on the ECAM is correct

OEB REMINDER

For aircraft that have the OEB Reminder Function activated, the L/G GEAR NOT DOWNLOCKED ECAM warning procedure and status may be flagged.
If the L/G GEAR NOT DOWNLOCKED ECAM warning procedure is flagged, the ECAM will display the "REFER TO QRH PROCline or "REFER TO QRH/OEB PROC"line (depending on Flight Warning Computer (FWC) standard) instead of the procedure itself.
To flag the procedure and the status that corresponds to the L/G GEAR NOT DOWNLOCKED ECAM warning, the following code must be entered in the FWC OEB database:

CODE	WARN	STS

OEB41 Issue 1.0
Associated with QRH OEB Proc N°: OEB41/1.0
ERRONEOUS ALTERNATE FUEL PREDICTIONS UPON MODIFICATION OF A COMPANY ROUTE IN THE ALTERNATE FLIGHT PLAN

Applicable to: B-HSQ, B-HSR

Approved by: Head of Flight Operations Support and Services

- This OEB covers a significant operational issue. Non-compliance with this OEB should have a significant impact on the operations of the aircraft. The Operators shall distribute its content to all flight crews without delay. An extract of this OEB is provided for insertion in the QRH.
- It is recommended that all Operators accelerate the incorporation of all corrective Service Bulletins as soon as they become available.

Reason for issue: This OEB replaces the A320 OEB 204.
This OEB is issued to inform the operators of the following: Erroneous alternate (ALTN) fuel predictions are experienced when the flight crew modifies a company route (CO RTE) previously inserted in the alternate Flight Plan (F-PLN).
This OEB provides an explanation and operational recommendations in case of erroneous ALTN fuel predictions.

Applicable to: Aircraft with Honeywell FMGC Release 1A "H2" (MOD 38778, Airbus SB A320 22-1269 and MOD 38779, Airbus SB A320 22-1270)

Cancelled by: Future Honeywell Standard MOD/Airbus SB to be determined later.

Note: The interchangeability code, given in the Illustrated Part Catalog (IPC), indicates the conditions for interchangeability of equipment. After installation of corrective modification(s)/SB(s), if an Operator reinstalls any equipment affected by this OEB, it is the Operator's responsibility to ensure that the recommendations given in this OEB are applied again for the applicable aircraft.

Operations Engineering Bulletins are issued by Airbus as the need arises to quickly transmit technical and procedural information. They are distributed to all FCOM holders and to others who need advice of changes to operational information.
Information in this bulletin is recommended by Airbus but may not be approved by Airworthiness Authorities. If the procedures contained in this OEB differ from the procedures in the AFM, the AFM remains the reference.

ERRONEOUS ALTERNATE FUEL PREDICTIONS UPON MODIFICATION OF A COMPANY ROUTE IN THE ALTERNATE FLIGHT PLAN

Applicable to: B-HSQ, B-HSR

EXPLANATION

When the flight crew modifies the CO RTE in the ALTN F-PLN, the FMS no longer computes the ALTN fuel predictions (refer to the below illustration).
This CO RTE could be extracted from the Navigation database or stored by the flight crew.
The modification of the CO RTE by the flight crew could be for example an entry of a departure or an arrival procedure.

The consequences of the CO RTE modification are:

- The fuel predictions are set to zero for the ALTN (solid circles) on FUEL PRED page (also on INIT FUEL PRED if done on ground)
  This condition is sufficient to apply the operational recommendations provided in the "PROCEDURE" paragraph.
- The Estimated Fuel On Board (EFOB) and the predicted UTC (solid circles) at ALTN destination becomes equal to the EFOB and the UTC at the Primary Destination
- If the ALTN fuel and the MIN DEST FOB values on FUEL PRED page are both at their default value (i.e. have not been modified by the crew), the MIN DEST FOB (solid circle) becomes erroneous (equal to FINAL instead of FINAL+ ALTN). Therefore, the MCDU scratchpad message "DEST EFOB BELOW MIN", is no longer triggered on the expected threshold
- If the flight crew had entered a value for the ALTN fuel, the entry is correctly used (but no more modifiable unless a new ALTN is entered)
- If the flight crew had manually entered the MIN DEST FOB value on FUEL PRED page (but not the ALTN fuel value), then the message "CHECK MIN DEST FOB"is no longer triggered at the correct threshold

Continued on the following page

ERRONEOUS ALTERNATE FUEL PREDICTIONS UPON MODIFICATION OF A COMPANY ROUTE IN THE ALTERNATE FLIGHT PLAN (Cont'd)

However, the new ALTN F-PLN is correctly displayed on the F-PLN page, the Navigation Display (ND) and the INIT page correctly shows the ALTN identifier.

Note: *The EFOB of the primary destination remains correctly computed (dashed circle).*

The reason for the anomaly is that when the ALTN CO RTE is modified, the FMS erroneously assumes there is no alternate F-PLN anymore for the fuel predictions. An additional modification of the ALTN F-PLN enables to recover correct ALTN fuel predictions.

PROCEDURE

This procedure only applies when a CO RTE is used for ALTN F-PLN. In the case of ALTN fuel predictions erroneously set to zero further to a modification of this ALTN F-PLN:

ENTER manually a waypoint in the en-route F-PLN (neither in the departure, nor in the arrival), to start a new computation of ALTN fuel predictions
Maintain or delete the entered waypoint at convenience
Check the ALTN fuel predictions are correct

CORRECTIVE ACTION

A future Honeywell FMS standard, will cancel this OEB (MOD and Airbus SB to be determined later).

TABLE OF CONTENTS

Introduction.....A

Intentionally left blank

INTRODUCTION

Applicable to: ALL

FCOM Bulletins were created to provide complementary technical/operational explanations related to the information included in the Flight Crew Operating Manuals (FCOMs).

The objective of FCOM Bulletins differs from that of Operations Engineering Bulletins (OEBs). OEBs are issued to rapidly address specific problems that have an operational impact. They are created, as needed, in order to quickly transmit technical and procedural information, and are normally issued in response to a detected irregularity or an abnormal aircraft/system behavior.

FCOM Bulletins are periodically issued to address one or several subjects and include supplementary explanations concerning procedures, system descriptions, performance, and regulations.

They are updated as the need arises and are filed in FCOM/FCB Flight Crew Bulletins.

OPERATION IN WINDSHEAR/DOWNBURST CONDITIONS

Intentionally left blank

FCB-FCB2-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Operation in Windshear/Downburst Conditions.....A

Intentionally left blank

OPERATION IN WINDSHEAR/DOWNBURST CONDITIONS

Applicable to: ALL

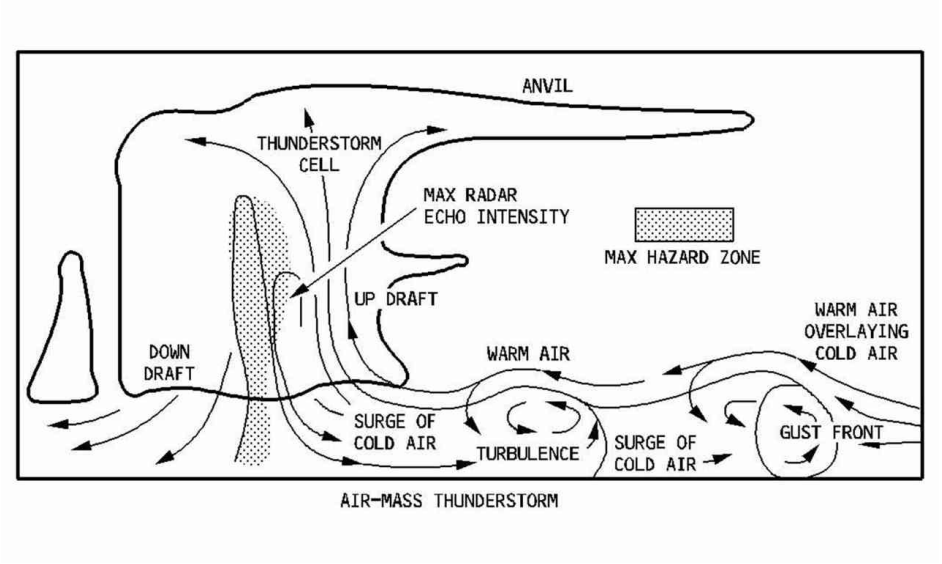
GENERALITY

Windshear-related problems are generally connected to "a change in wind direction and/or speed over a very short distance in the atmosphere". The most prominent meteorological conditions conducive to this are:

- Convective storm shear (air mass and frontal thunderstorms, downburst, wet and dry microburst)
- Non-convective (cold and warm) frontal systems
- Windshear associated with strong winds near the ground.

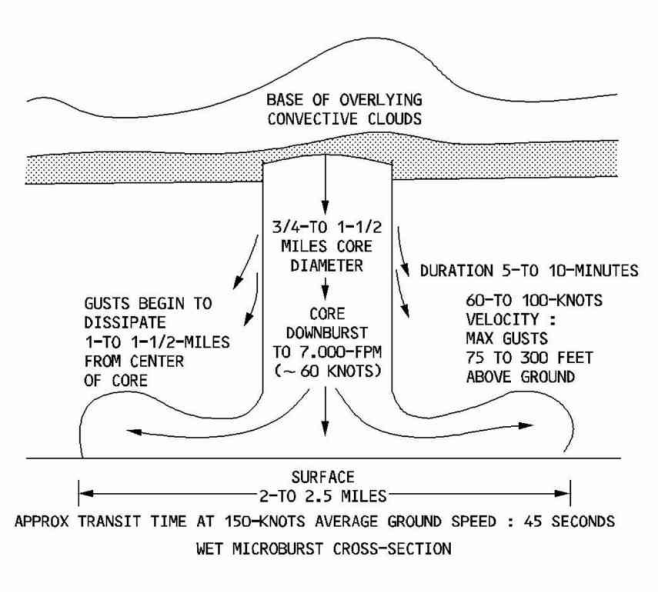
WINDSHEAR ASSOCIATED WITH CONVECTIVE CLOUDS AND STORM CELLS

- The air-mass thunderstorm develops from localized earth surface heating with air rising and cooling to form cumulus clouds. As these keep growing, heavy rain and hail precipitation begins to develop in the higher areas thereby cutting off the updraft energy source and eventually dissipating the thunderstorm cell. A surge of cold air emerging from the heavy rain and associated downdraft can produce:
  - A downburst, i.e. strong downdrafts inducing an outburst of damaging winds on or near the ground
  - A gust front with blowing dust on the earth surface
  - A shear boundary with turbulent flow due to interaction with the warm, undisturbed environmental air.



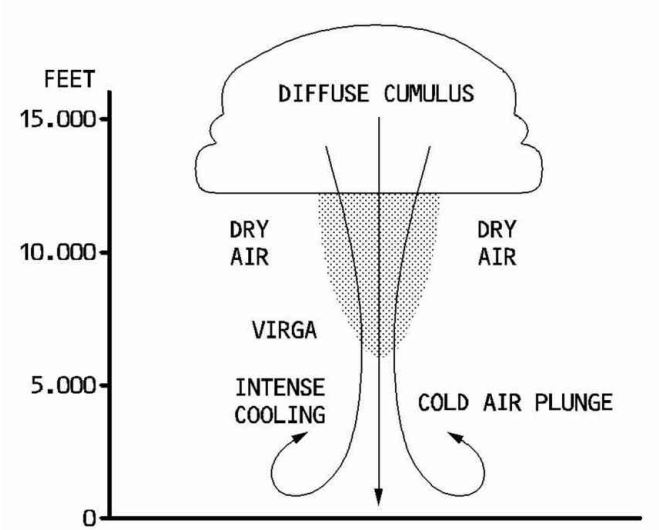
AIR-MASS THUNDERSTORM

- Frontal thunderstorms are usually more tilted in the vertical, allowing precipitation to fall away from the updraft and airflow intensity within the storm accelerating much more than for the simple air-mass thunderstorm, sometimes resulting in a tornado.
- Microbursts consist of intense, non rotating, highly localized downward airflows with velocities up to 7 000 fpm that may emanate below a convective cloud base. Some of these microbursts will expose penetrating aircraft to major safety hazards whatever technique is used in anticipation/reaction.



Microbursts can take 2-5 min to develop maximum intensity and may then be sustained for an equal period of time. They tend to develop in groups which may be merged, delaying dissipation to 30 min. Present knowledge contends that approximately one in a hundred heavy rain thunderstorms produce microbursts. It was determined that microbursts can also occur in relatively dry conditions. Once it gains sufficient downward momentum, a downflow with evaporative cooling accelerates to the earth's surface to induce a "dry microburs" with very light or non-existant precipitation, called virga. "Wet microburst" are expected to occur in the wet regions of the world. Dry microbursts are commonly seen in the dry areas and most likely below cumulus cloud when dew point is 30 °C or more below ambient temperature.
Changes in meteorological conditions associated with both macro and microbursts tend to be very complicated.

CONDITIONS	MACROBURSTS	MICROBURSTS
Air temperature	ISA + 15 °C decreasing	ISA + 15 °C increasing or decreasing
Dew point spread	Increase (20-40 °C)	Increase (20-40 °C)
Surface pressure	Rise or fall (up to 2/3 mb)	Rise or fall (up to 2/3 mb)



DRY MICROBUST CROSS-SECTION IN VIRGA

WINDSHEAR ASSOCIATED WITH NON-CONVECTIVE FRONTAL SYSTEMS

Substantial differences in winds can be encountered by approaching and departing aircraft close to low pressure centers and their associated cold, warm and occluded fronts.
Penetrating a cold front on either side leads to a headwind increase, potentially bringing a performance increasing shear. Pilots are advised to beware of thunderstorms in the vicinity that may contribute to amplify windshear conditions.
Penetrating a warm front on either side exposes to a headwind decrease, potentially resulting in a performance decreasing shear generally not exceeding performance limits of the aircraft. Windshear at a warm front is more severe than at a cold front with large head/tail and vertical wind changes in the lowest 1 000 ft above ground level.

The magnitude of the windshear may become significant when:
- The temperature difference across the front is at least 6 °C
- The temperature gradient of the front shows a minimum of 6 °C over 50 nm
- The speed of frontal movement is greater than 30 kt.

WINDSHEAR ASSOCIATED WITH STRONG WINDS NEAR THE GROUND

Very similar to a surface boundary layer with increasing winds and approximately constant wind direction.

Low altitude jet streams may be found in a variety of situations such as strong low altitude jet winds, nocturnal jet winds, terrain-induced low altitude windshear, mountain-wave and downslope flows, strong surface winds combined with small hills or large buildings, lake and seabreeze windshear due to temperature gradients between sun-heated terrain and water-cooled air. In particular, strong temperature change across an inversion may trigger very variable wind conditions.

DETECTION OF CONDITIONS

OPTIONAL SYSTEMS INTEGRATED ON THE AIRCRAFT

Predictive Windshear

Predictive Windshear is incorporated into the weather radar system to enable the detection of a microburst windshear event within 5 nm forward of the aircraft. It is based on dynamic Doppler effects.
When a windshear is detected, the system generates the appropriate annunciation to the crew to alert them of a potential danger.

There are different alert levels depending on:
- The severity of the windshear event detected
- The distance and angular position between the aircraft and the windshear
- The altitude and speed of the aircraft
- The flight phase.

The Predictive Windshear system provides advanced warning for the crew to escape a windshear event using normal handling technique or to initiate a recovery maneuver earlier.

Reactive Windshear

Reactive Windshear advises the crew when windshear conditions have been entered. The system generates an audio and visual warning to the crew. The FAC measures the difference between the impredicate energy state and the minimum energy state for flight security.

At a defined threshold, a message is displayed on the PFD and an aural warning alert is provided to the crew:
- At takeoff, from 5 s after lift off up to 1 300 ft RA
- At landing, from 1 300 ft RA down to 50 ft RA.

BRIEFING AND PREPARATION

a. ANALYSE weather information during preflight:
   - Weather messages provided by the airline
   - Aviation surface observations
   - NOTAMS
   - SIGMETS, particularly convective sigmets

- Terminal forecasts
- Area forecasts, possibly mentioning the Low Level Wind Shear Alert System (LLWSAS) installed on the periphery of certain airports (USA only).

b. LISTEN to pilot reports (PIREPS) on wind shear. PIREPS should include:
- Location of shear encountered
- Altitude of shear encountered
- Airspeed change experienced (knots gained or lost)
- Type of aircraft undergoing the shear.

Note: Pilots should always report any windshear encountered to Air Traffic Control.

c. LOOK OUT for weather clues on the way to the airport and/or from the cockpit (parked, taxi or airborne) such as:
- Extreme variations in wind velocity/direction in a very short time span
- Isolated rainshowers with or without lightning showing divergences from the raincore and clear curling horizontal vortex rolls, within 5 miles of the airport
- Heavy precipitation along intended flight path
- Lightning, thunderstorms or evidence of any tornadic feature in airport vicinity
- Evidence of a gust front such as blowing dust on the airport surface, suggesting the possible passage of a thunderstorm within 15 min
- Evidence of convective activity particularly with anvil clouds in dry areas, supercells, low echos, mushroom, sinkhole and/or giant ant-eater clouds, cumulo nimbus mamatus and altocumulus.

Note: The existence of other types of shear can occur due to local obstruction, topographical and meteorological conditions. It is important for crews to realize that windshear conditions should be considered cumulative: simultaneous conditions can increase the severity of effects.

d. EXAMINE the approach or take-off area with the airplane weather radar to determine whether returns are in the vicinity of the airport or intended flight path:
   - Flight operations below 10 000 ft such as take-off and landings require 2 to 3 ° upward tilt for target detections up to 40 nm; if there is significant weather activity, the tilt angle should be adjusted to provide a solid ground return outside of the desired range to ensure that no overscanning will occur.

     Note: Since radar echoes are due to precipitation reflection, dry environment situations and conditions to dry microbursts may not be detectable by weather radar.

e. MONITOR the aircraft instruments whenever windshear is suspected:
   - Any rapid change in the relationship between airspeed and groundspeed represents a windshear; groundspeed must be compared with airspeed, on the ND's. (GS/TAS)
   - Airspeed tendency (Vc trend):
     • Acceleration in headwind/updraft
     • Deceleration in tailwind/downdraft.
   - Direction and intensity of wind (computed by the IRS and displayed on ND's) allows a comparison at the initial approach altitude (1 500 ft to 2 000 ft AGL), with the reported runway surface wind to check any shear situation between the airplane and the runway
   - Speed margin from α-prot speed (shown by a red and amber strip along the speed scale of the PFD's)
   - Rate of descent (on stabilized ILS approach):
     • High rate suggesting a strong tailwind
     • Low rate suggesting a strong headwind.
   - Rate of climb:
     • High rate suggesting a strong headwind
     • Low rate suggesting a strong tailwind.
   - Pitch attitude:

Increasing	With headwind shear
	With downdraft shear.
Decreasing	With tailwind shear
	With updraft shear.

   - Power needed:

     To hold the glideslope:
     • Less power necessary suggesting a strong tail wind
     • More power necessary suggesting a strong headwind.

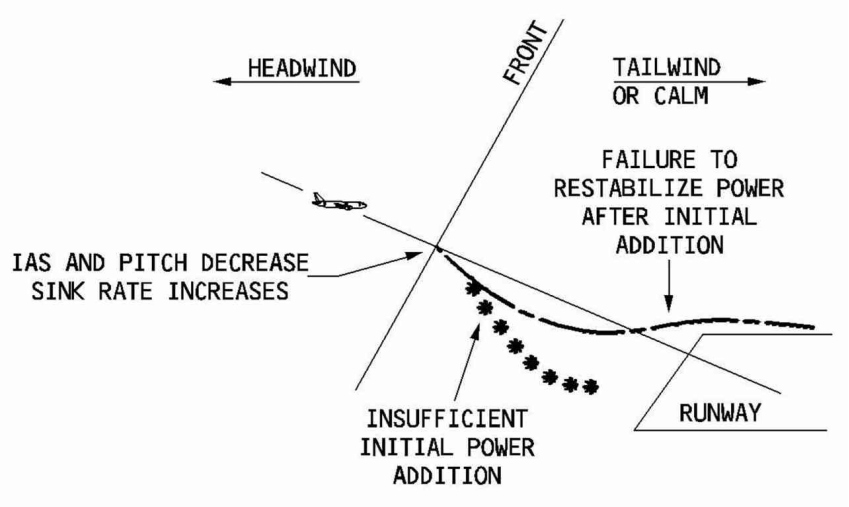
     To hold a climb angle:
     - Less power necessary suggesting a strong headwind,
     - More power necessary suggesting a strong tailwind.

INFLUENCE OF WINDSHEAR ON AIRCRAFT PERFORMANCE

DECREASED PERFORMANCE

Headwind to tailwind
Headwind to calm
Calm to tailwind
Headwind to decreased headwind.

Approach with a Tailwind Shear



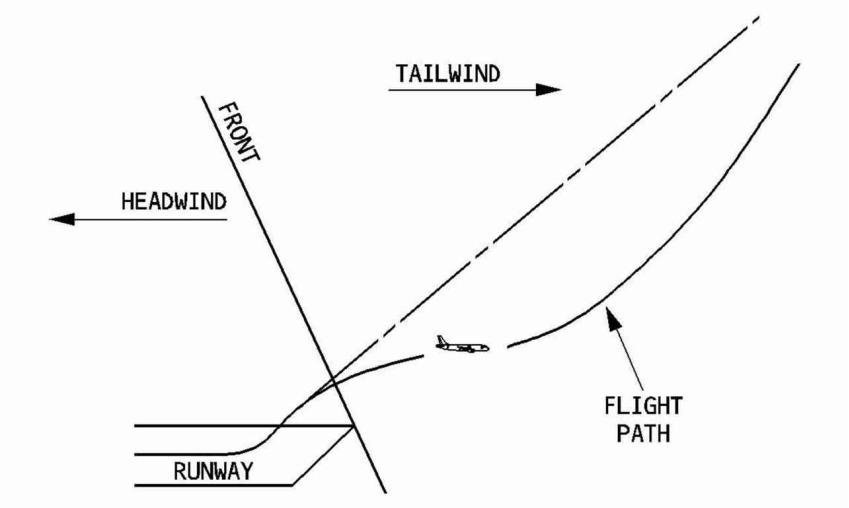
- Airspeed decreases, lift decreases
- A/C nose begins to pitch down
- A/C begins to drop below the glide slope

In this case the A/C is both slow and low in a "power deficient" state.

Consequences

- If the pilot pulls the nose up to recapture the glide slope without selecting sufficient power:
  The A/C will loose altitude very rapidly and may even reach the ground before the power deficiency is corrected, resulting in a hard landing, or
- If sufficient power is set to regain the glideslope before reaching the ground:
  The "double negative" problem may arise if the pilot does not quickly retard the throttles after glide recapture, i.e. throttles set too high for a stabilized approach in a no-wind condition leading to a long and fast landing.

Take Off with a Tailwind Shear



- Airspeed decreases, lift decreases
- A/C nose begins to pitch down
- A/C drops below its nominal flight path.

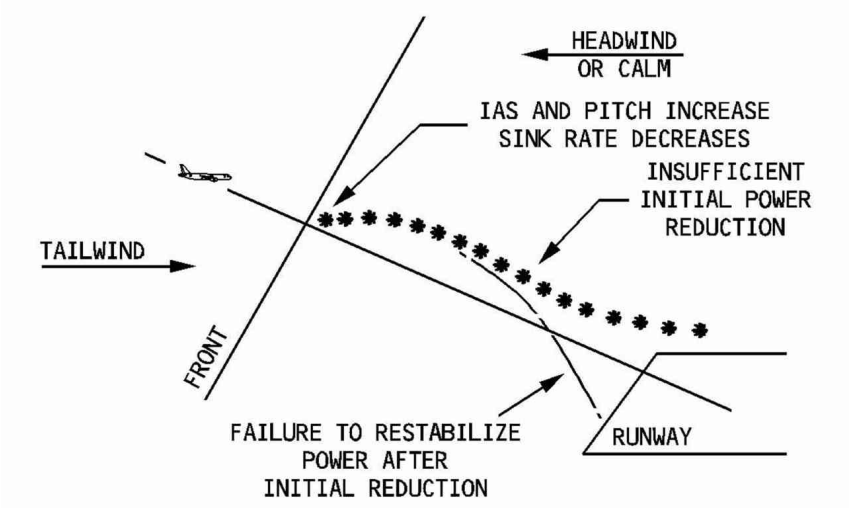
Consequences

- Because of aircraft inertia, attitude and ground speed will be initially maintained upon encountering windshear but airspeed will decrease, causing a reduction in lift which will result in a downward acceleration and a nose down pitching moment.
- If there is no pilot action, the aircraft will descend below its nominal flight path. Because of aircraft stability, original angle of attack and airspeed will eventually be recovered, but on a reduced flight path.

INCREASED PERFORMANCE

Tailwind to headwind
Calm to headwind
Tailwind to calm
Headwind to increased headwind

Approach with a Headwind Shear



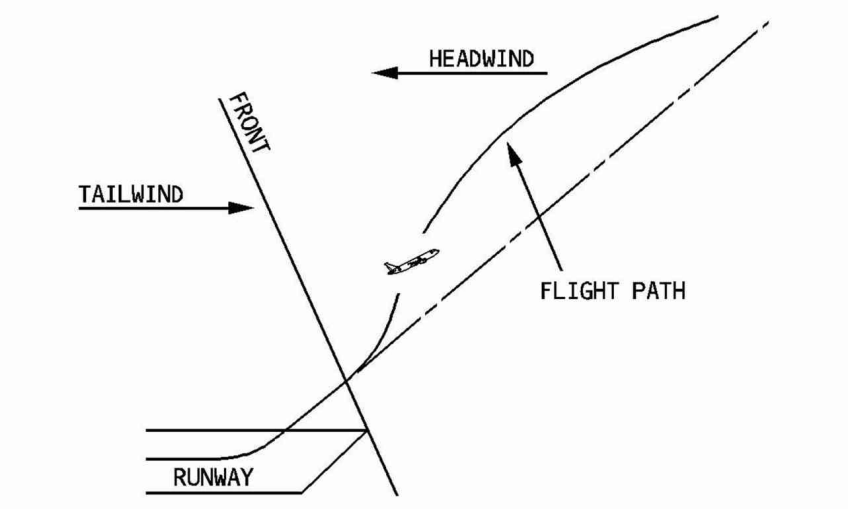
The reverse of the previous case prevails:
- Airspeed increases, lift increases
- A/C nose begins to pitch up
- A/C balloons above the glide slope.

In this case the A/C is both fast and high in a "power excessive" state.

Consequences

- The pilot does not initially reduce power, the aircraft will gain altitude and airspeed resulting in a long, fast landing with the possibility of an overrun, or
- If the pilot reduces thrust to regain the glideslope and initial airspeed: the "double negative" problem can arise if the thrust is not recovered which leads to a high sink rate and possible short, hard landing.

Take Off with a Headwind Shear



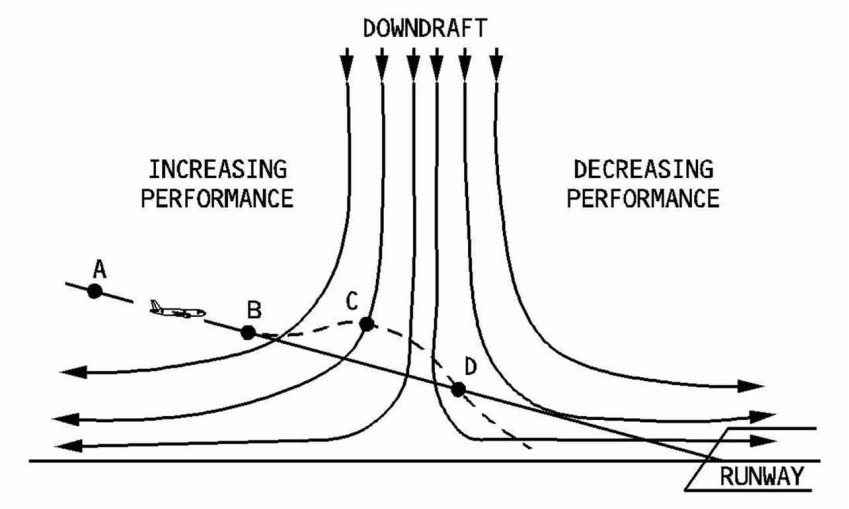
The reverse of the previous case prevails:
- Airspeed increases, lift increases
- A/C nose begins to pitch up
- A/C rises above its nominal flight path.

Note: - *A headwind shear usually leads to increased aircraft performance.*
- *The resulting increase in lift may however lead to an excessive angle of attack which could eventually trigger the α-prot function once out of the shear.*

INCREASED PERFORMANCE FOLLOWED BY DECREASED PERFORMANCE

Downdraft + tailwind shear

Approach through Microburst

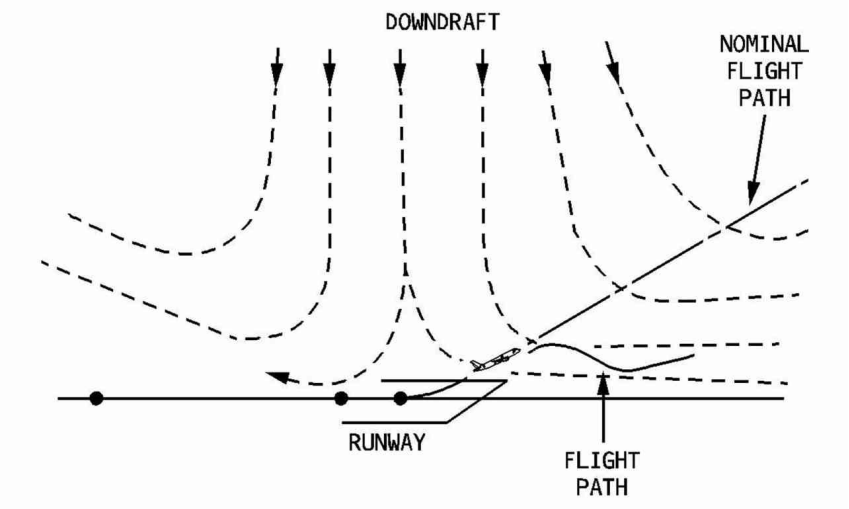


- At point A the aircraft is on speed and on glide slope.
- At point B it encounters an increasing headwind. Its airspeed and pitch increase and it balloons above the glide slope.
- At point C the "moment of truth" occurs:
  If the pilot does not fully appreciate the situation, he may attempt to regain the glide slope by reducing power and pushing the nose down.
  But between C and D the headwind ceases, a strong downdraft is entered and the tailwind begins to increase. The skin rate occurs rapidly and ground impact may become difficult to avoid.

Consequences

- A go-around initiated at point C or sooner would probably be successful since the A/C is fast and high at this point.
- Gradual groundspeed decay shortly after point B coupled with rapidly increasing airspeed could have allowed detection of signs of impending downdraft.

Take Off through Microburst



- Airspeed decreases
- A/C nose begins to pitch down
- A/C drops below its nominal flight path.

Consequences

- Initially the pilot may not fully appreciate the situation since he is taking off in increased performance shear conditions. Progression into the downburst core causes a violent and rapid loss of lift, followed by a high sink rate with very little loss of airspeed. Exiting the downburst core below the nominal flight path (after 20 to 40 s) is then followed by a low-level decreased performance tailwind shear
- In this microburst example, the angle of attack is instantly decreased causing an immediate loss of lift.

CLIMB GRADIENT AND ACCELERATION CAPABILITY

This section presents an example of A/C ability to maintain an horizontal flight at a given airspeed, in case of tailwind shear or downdraft conditions by adjusting the thrust.
In practice, windshear conditions will very often be a combination of horizontal and vertical shear components.

This will make it necessary to establish a tradeoff between climb gradient and acceleration requirements.
a. Acceleration capability

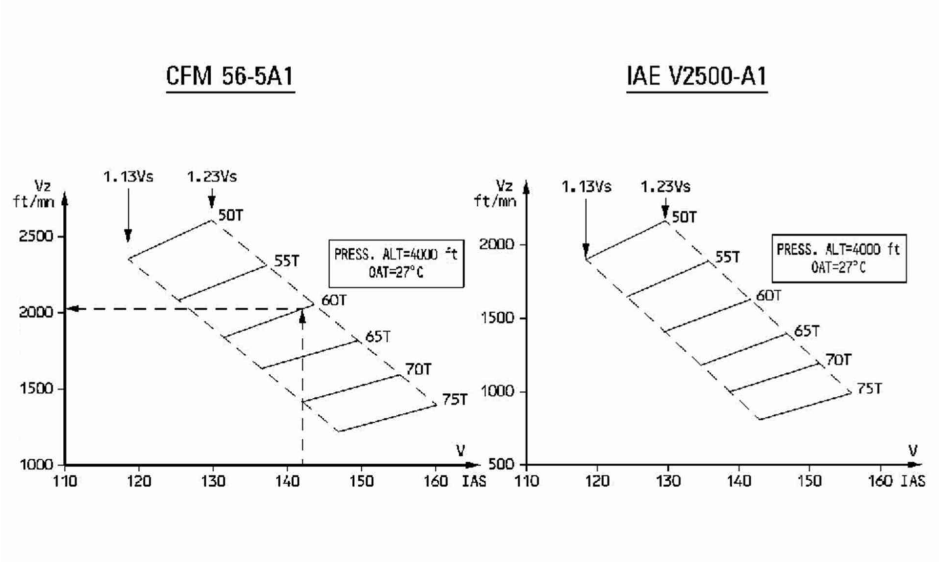
In case of tailwind shear, the aircraft oppose a level flight acceleration capability. For example, an A320 powered with CFM56-5A1 engines (A/C weight = 60 000 kg (132 300 lb), FLAPS 3, pressure altitude = 0 ft, OAT at ISA) is able to maintain an horizontal flight in a 4 kt/s decreased performance shear, keeping a constant airspeed and increasing ground speed of 4 kt/s.

If the horizontal shear exceeds the flight level acceleration, the airspeed will decrease and will descend unless pitch attitude is increased.

b. Climb gradient maintainability

In downburst conditions, level flight will be maintained with the climb gradient maintainability. In the following example (CFM 56-5A1, A/C weight = 60 000 kg (132 300 lb) pressure altitude 4 000 ft, OAT = 27 °C, V = 142 kt), the aircraft has the capability to maintain level flight in a 2 040 ft/min downdraft without any airspeed change. If the downdraft exceeds this climb gradient capability, the A/C will descend unless pitch attitude is increased to adapt angle of attack.

For information, a typical example:



FLIGHT CREW BULLETINS

IAE V2500 N1 MODE

Intentionally left blank

FCB-FCB3-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

IAE V2500 N1 Mode..... A

Intentionally left blank

IAE V2500 N1 MODE

Applicable to: ALL

The FADEC NORMAL mode is EPR mode which requires various inputs including:
- Thrust Lever Angle (TLA) altitude
- Mach number
- Ambient temperature
- Engine inlet total air temperature (T2), and
- The service bleed.

If any of these inputs are not available, the FADEC automatically reverts to a reversionary which may be:
- N1 RATED mode
- N1 UNRATED mode (named DEGRADED mode on ECAM).

N1 RATED MODE

DESCRIPTION

The N1 RATED MODE is a FADEC reversionary mode which occurs:
- Either AUTOMATICALLY if P2 (engine inlet total pressure) and/or P5 (LP turbine exit total pressure) engine parameters are not available, or
- MANUALLY if the pilot presses the N1 MODE pb.

The FADEC, in this mode, processes the N1 power management as a function of TLA, T2 and altitude, for the following ratings:
- MAX TO or GO AROUND
- MAX CONTINUOUS
- MAX CLIMB.

Additionally the FADEC provides the following data to the crew via ECAM E/W display:
- N1 rating limit corresponding to the selected Thrust Limit mode (CLB, MCT, TO)
- Selected THRUST LIMIT mode as a function of TLA
- N1 TLA corresponding to the thrust lever position
- Actual N1.

OPERATIONAL CONSEQUENCES

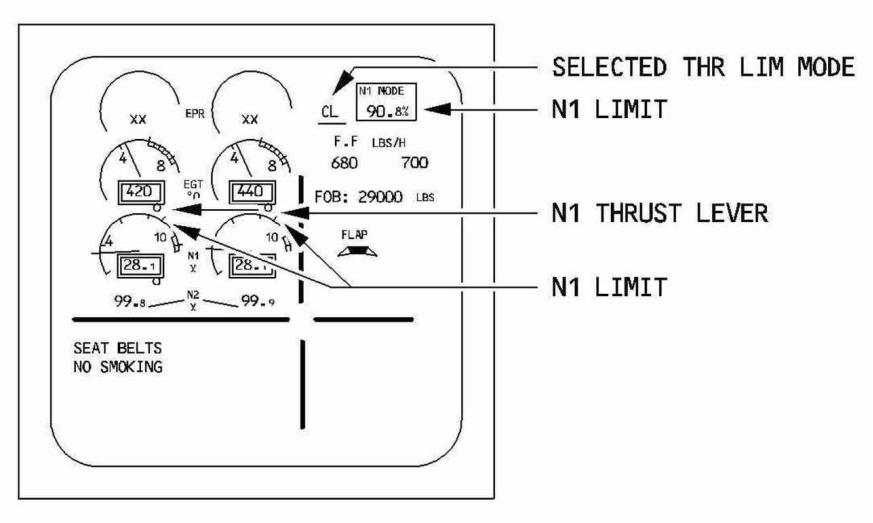
1. Reversion from EPR →N1 RATED mode on the GROUND:
   - This is a GO ITEM (please *Refer to MEL/MI-73-20 EPR Control Mode*)
   - Autothrust control is lost and thus alpha-floor protection is not available

- Performance penalties must be applied (please *Refer to MEL/MO-73-20 EPR Control Mode*):
  - For takeoff MAX weights and associated speeds
  - For single engine cruise, drift down net ceiling.
- Flexible takeoff is not permitted.

2. Reversion from EPR →N1 RATED mode during T/O Phase:
   The thrust remains EQUIVALENT to the thrust initially obtained with EPR mode, up to 2 500 ft above runway level.
3. Reversion from EPR →N1 RATED mode in FLIGHT:
   A cockpit caution and audio message are triggered with the associated ECAM procedure "EPR MODE FAULT".
   In addition, the A/THR will disengage and the alpha floor will be lost. If the thrust levers were in the CLB detent (MCT for single engine operation), the THRUST LOCK function will be activated. It will be deactivated as soon as a thrust lever is moved from the CLB (MCT) detent.

Note: *No particular precautions are required when pressing the N1 MODE pb.*

The ECAM E/W display correct data on the N1 indicator, when N1 RATED MODE is active for both engine.



N1 UNRATED MODE

DESCRIPTION

The N1 UNRATED MODE reversion occurs in the event of the loss of the engine inlet total air temperature (T2) or the ambient temperature (ambient pressure engine sensor).
The N1 is defined as a function of TLA only and is limited by the FADEC to either the lower of maximum N1 or N1 redline (if T2 is available) or N1 redline (if T2 is not available).
The only data provided to the crew by the FADEC is:
N1 ACTUAL

There is a difference between N1 provided in EPR MODE or N1 in RATED MODE and UNRATED MODE, for a given TLA. As a consequence, switching from EPR to N1 UNRATED may result in a N1 change:

- In case the reversion occurs when A/THR is engaged and thrust levers are out of a detent or subsquently moved out of a detent
- When pressing the N1 MODE pb.

OPERATIONAL CONSEQUENCES

1. If reversion to N1 UNRATED MODE occurs on the GROUND:
   This is a NO GO ITEM.
2. If reversion occurs in FLIGHT:
   A cockpit caution and audio message are triggered with an ECAM procedure. Please *Refer to PRO-ABN-70 ENG 1(2) EPR MODE FAULT*, to have the detail of the corresponding ECAM procedure.

   Additionally the A/THR will disengage and alpha-floor protection will be lost:
   - If thrust levers were in CLB detent (or MCT notch with one engine INOP), the THRUST LOCK function will be activated. Moving thrust levers or depressing the N1 MODE pushbutton will cause the THRUST LOCK system to be deactivated and N1 will follow TLA position.
   - If thrust levers were not in CLB/MCT notches, the N1 change would occur immediately.

   In the case both FADECs revert to N1 UNRATED MODE, in order to ensure a proper power management and satisfy N1 LIMIT values, N1 tables are provided in FCOM:
   - "Thrust ratings", N1 MCT, *Refer to PER-THR-N1 N1 MODE THRUST CONTROL*
   - N1 MAX CLB, *Refer to PER-THR-N1 MAXIMUM CLIMB N1*
   - N1 MAX CRZ, *Refer to PER-THR-N1 MAXIMUM CRUISE N1*
   - N1 GO AROUND, *Refer to PER-THR-N1 MAXIMUM GO AROUND N1*.

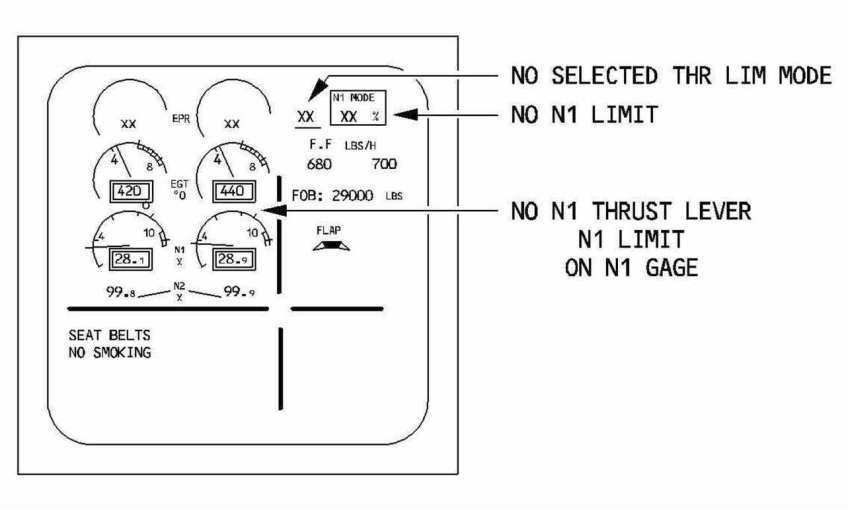
   Furthermore SINGLE ENG DRIFT ON NET CEILING penalties will be also published there.
3. It would be more likely to have a MIXED CASE where a failure is experienced on one engine, while the other is working normaly. If this occurs, the CAUTION/AUDIO/ECAM messages will be identical except for one additional message (NOT EXCEED N1 LIMIT): Indeed both N1

MODE pb will have to be pressed so as to help the crew to properly adjust the ACTUAL N1 on the engine where the FADEC is in N1 UNRATED MODE, by using the data provided by the other FADEC (N1 ACTUAL, N1 LIMIT). As a consequence, the crew will have to adjust the thrust lever, on the failed side, to a position (which depends on flight conditions) so as to align its N1 ACTUAL to the other N1 ACTUAL provided on ECAM. In this case there will be a thrust lever misalignment.

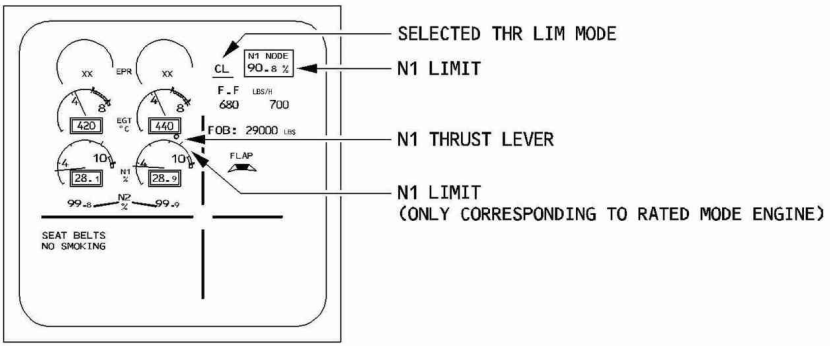
Single engine cruise drift down net ceiling penalties should also be used, in case that a subsequent engine failure occurs.

4. The ECAM E/W display indicates the following data on the N1 gage, depending upon 2 FADECs in N1 UNRATED mode, or 1 FADEC in N1 RATED and the other in N1 DERATED mode

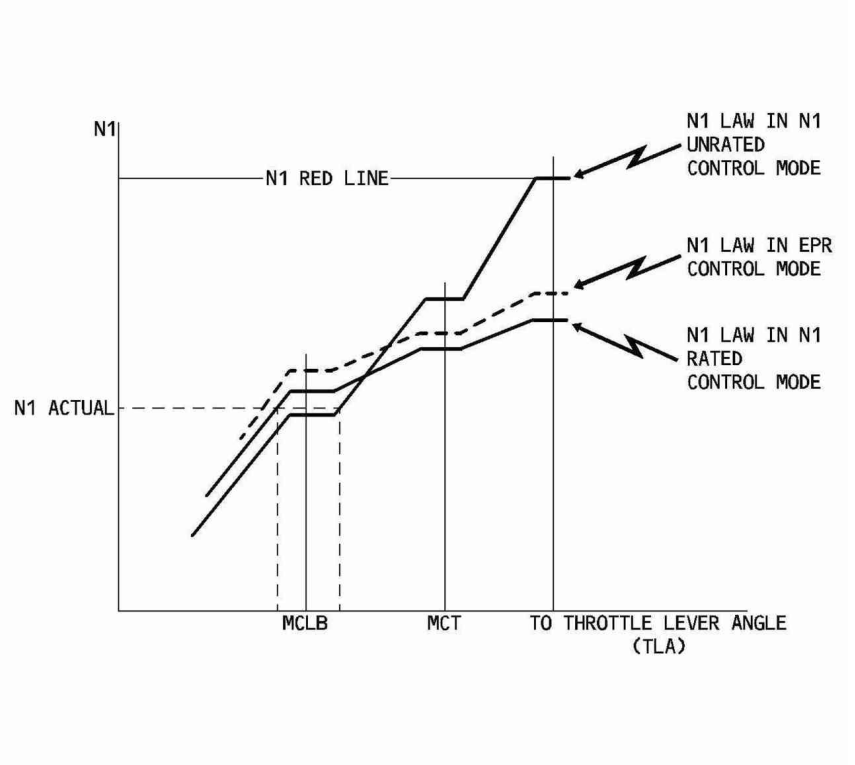
2 FADEC N1 DEGRADED MODE



MIXED CASE: ENG 1 Degraded, ENG 2 Rated mode



N1 COMMAND VERSUS THRUST LEVER POSITION RELATIONSHIP



This figure indicates that, in the MIXED case, the thrust lever position on both engines will be quite different in order to achieve the same N1 actual:

- For example in order to achieve an N1 actual lower than MAX CLB.
  - The thrust lever position on the side where FADEC is in UNRATED mode may be FORWARD of MAX CLB notch, while
  - The thrust lever position on the side where FADEC is in RATED mode is systematically AFT of MAX CLB notch.

FLIGHT CREW BULLETINS

AVOIDING TAILSTRIKES

Intentionally left blank

FCB-FCB5-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Avoiding Tailstrikes..... A

Intentionally left blank

AVOIDING TAILSTRIKES

Applicable to: ALL

Inadvertent tailstrikes may occasionally occur, and may result in expensive structural damage. Several tailstrikes have been reported throughout service life.
They are very often associated with such adverse conditions as crosswind, turbulence, windshear, etc.

A/C GEOMETRY LIMITS

Two limits need to be considered:
- The geometry limit corresponding to the main gear oleo fully extended (θ1)
- The geometry limit corresponding to the main gear oleo fully compressed (θ2).
  Example:

	PITCH ATTITUDE θ			
MAIN GEAR OLEO POSITION	**A318**	**A319**	**A320**	**A321**
FULLY EXTENDED	17.3 °	15.5 °	13.5 °	11.2 °
FULLY COMPRESSED	15.7 °	13.9 °	11.7 °	9.7 °

Note: On the A321, the installation of a TFTS antenna decreases these values.

CLEARANCE AT TOUCHDOWN

The following table provides the ground clearance in degrees for the A318, the A319, the A320, and the A321 at landing (all numbers are mean values).

AIRCRAFT	GEOMETRY LIMIT AT TOUCHDOWN	PITCH ATTITUDE AT VAPP (VREF + 5)(1)	PITCH ATTITUDE AT TOUCHDOWN (VAPP - 8)(2)	CLEARANCE(3)
A318	17.3 °	3.2 °	7.8 °	9.5 °
A319	15.5 °	3.4 °	7.7 °	7.8 °

Continued on the following page

Continued from the previous page

AIRCRAFT	GEOMETRY LIMIT AT TOUCHDOWN	PITCH ATTITUDE AT VAPP (VREF + 5)(1)	PITCH ATTITUDE AT TOUCHDOWN (VAPP - 8)(2)	CLEARANCE(3)
A320	13.5 °	3.3 °	7.6 °	5.9 °
A321	11.2 °	2.4 °	6.6 °	4.6 °

(1) Flight path in approach = -3 °

(2) Mean value of pitch attitude at touchdown, assuming a deceleration of 8 kt during flare (VAPP -8), and a flight path of -1 ° at touchdown (approximately 3 ft/s).

(3) Clearance = Geometry limit-Pitch attitude at touchdown.

When the approach speed is decreased by 5 kt, clearance decreases by approximately 1.3 ° (attitude at touchdown increases by 1.3 °).

TAILSTRIKE FACTOR AT TAKEOFF

Early rotation, over-rotation, excessive pitch rate, or a combination of these three factors are the main causes of tailstrikes at takeoff.

EARLY ROTATION

Early rotation occurs, when:
- A too low VR is computed
- The rotation is initiated prior to VR.

Erroneous VR computation may occur, when the takeoff speeds are not crosschecked, or an incorrect loadsheet data is used. At hot-and-high elevation airfields, the error can be critical.

Rotation initiated prior to VR due to:
- Flaps improperly set for the calculated VR
- Bird or obstacle avoidance leading to early rotation
- Early rotation due to windshear, encountered during the takeoff roll. In such an event, the FAA recommends rotation, 2 000 ft before the end of the runway.

OVER-ROTATION OR EXCESSIVE PITCH RATE

These two causes are generally associated with a second factor in tailstrike incidents (one engine-out, aircraft out of trim, additive inputs from both pilots, early rotation, etc.).
Certification requires demonstration of a safe takeoff at VR -10 kt (2 engines) and VR -5 kt (1 engine).
The pitch and the pitch rate, obtained during these tests, are for information purposes only, and are not certified limits.

AIRCRAFT	WEIGHT (kg)	CG	CONFIG.	ROTATION SPEED	θ°PER SEC	θ°AT LIFT-OFF
A318 CFM	60 145	15.6 %	CONF 2	VR -10 kt 2 engines	5.9 °/s	10.6 °
	61 725	15.4 %	CONF 3	VR -5 kt 1 engine-out	5.3 °/s	9.8 °
A319 CFM	62 550	21.4 %	CONF 2	VR -10 kt 2 engines	5.8 °/s	12.5 °
	63 440	21.3 %	CONF 2	VR -5 kt 1 engine-out	5.9 °/s	12.8 °
A320	67 200	17.8 %	CONF 2	VR -10 kt 2 engines	5.8 °/s	9.5 °
	65 300	116.5 %	CONF 2	VR -5 kt 1 engine-out	5.4 °/s	9.0 °
A321 IAE	75 950	14.9 %	CONF 2	VR -10 kt 2 engines	6.3 °/s	8.5 °
	73 720	15.0 %	CONF 2	VR -5 kt 1 engine-out	5.4 °/s	9.0 °

Note: VR represents the speed at aircraft rotation, in order to obtain V2 at 35 ft, in the event of an engine failure.

Normal rotation of 3 °/s prevents a tailstrike, unless the rotation is initiated at a speed which is far too low. This rotation is obtained in 5 to 6 s for an average 15 ° to 18 ° takeoff attitude.

TAILSTRIKE AT LANDING

Industry statistics show that tailstrikes are more likely to occur at landing, than at takeoff (2 to 1). Although most of them are due to deviations from normal landing techniques, some are associated with such external conditions as turbulence and wind gradient.

DEVIATION FROM NORMAL LANDING TECHNIQUES

Deviations from normal landing techniques are the most common causes of tailstrikes, the main reasons for this being:

a. Allowing speed to decrease well below VAPP before flare.
   Flying at a too low speed means high a AOA and high pitch attitude, thus reducing ground clearance. When reaching the flare height, the pilot will have to significantly increase the pitch to reduce the sink rate. This may lead the pitch to go beyond the critical angle.
b. Prolonged hold-off for a smooth touchdown
   As the pitch attitude increases, the pilot needs to focus further ahead to assess the aircraft's position in relation to the ground. The attitude and distance relationship can lead to a pitch attitude increase beyond the critical angle.
c. Too high flare

A high flare can result in a combination of decreased airspeed and long float. Since both lead to increased pitch attitude, the result is reduced tail clearance.

d. Too high a sink rate, just prior reaching the flare height.
In case of a too high sink rate close to the ground, the pilot may attempt to avoid a firm touchdown by commanding a high pitch rate.
This action will significantly increase the pitch attitude and, as the resulting lift increase may be insufficient to significantly reduce the sink rate, a firm touchdown may occur. In addition, the high pitch rate may be difficult to control after touchdown, particularly in case of bounce.

e. Bouncing at touchdown
In case of bouncing at touchdown, the pilot may be tempted to increase the pitch attitude so as to ensure a smooth second touchdown. If the bounce results from a firm touchdown associated with a high pitch rate, it is important to control the pitch so that it does not further increase beyond the critical angle.

APPROACH AND LANDING TECHNIQUES

A stabilized approach is essential for achieving successful landings. It is imperative that the flare height be reached at the appropriate airspeed and flight path angle. A/THR and FPV are effective aids to the pilot.
The VAPP should be determined with the wind corrections, given in FCOM/QRH, using FMGS functions.
As a reminder, when close to the ground, the wind intensity tends to decrease and the wind direction to turn (direction in degrees decreasing in northern latitudes).
Both effects may reduce the headwind component close to the ground, and the wind correction to Vapp is there to compensate this effect.
When close to the ground, high sink rates should be avoided, even in an attempt to maintain a close tracking of the glideslope. Priority should be given to attitude and sink rate. If a normal touchdown distance is not possible, a go-around should be performed.
If the aircraft has reached the flare height at VAPP with a stabilized flight path angle, the normal SOP landing technique will lead to repetitive touchdown attitude and airspeed.
Assuming an 8 kt speed decrease during flare, and a -1 ° flight path angle at touchdown, the pitch attitude will increase by approximately 4.5 °.
During flare, the pilot should not concentrate on the airspeed, but only on the attitude with external cues.

Note: *Airspeed indication during flare is influenced by the static error due to the ground effect.*

The PNF should monitor the pitch attitude on the PFD and call "PITCH", whenever the following pitch value is reached:

- For the A318/A319/A320 : 10.0 °
- For the A321 : 7.5 °

After touchdown, the pilot must "fly" the nosewheel smoothly, but without delay, on to the runway, remaining prepared to counteract any residual pitch up effect of the ground spoilers.

Note: The main part of the spoilers' pitch up effect is compensated by the flight control laws.

BOUNCING AT TOUCHDOWN

In case of a light bounce, maintain the pitch attitude and complete the landing, while keeping thrust at idle.
Do not allow the pitch attitude to increase, particularly following a firm touchdown with a high pitch rate.
In case of a high bounce, maintain the pitch attitude and initiate a go-around.
Do not try to avoid a second touchdown during the go-around. Should it happen, it would be soft enough to prevent damage to the aircraft, if pitch attitude is maintained.
Only when safely established in the go-around, retract flaps one step and the landing gear.
A landing should not be attempted immediately after a high bounce, as thrust may be required to soften the second touchdown, and the remaining runway length may be insufficient to stop the aircraft.

FQI Accuracy..... A

Intentionally left blank

FQI ACCURACY

Applicable to: ALL

INTRODUCTION

The FQI system installed on Airbus aircraft use probes to measure the quantity of fuel in the different fuel tanks.
Each FQI probe consists of two fixed concentric tubes which form the plates of a capacitor.
The dielectric of this capacitor is provided by air and fuel which have different dielectric constants.
Therefore the capacitance of a vertically installed probe varies with the fuel level and gives an indication of fuel quantity in the tank.

FQI ACCURACY ON AIRBUS INDUSTRIES PRODUCTS

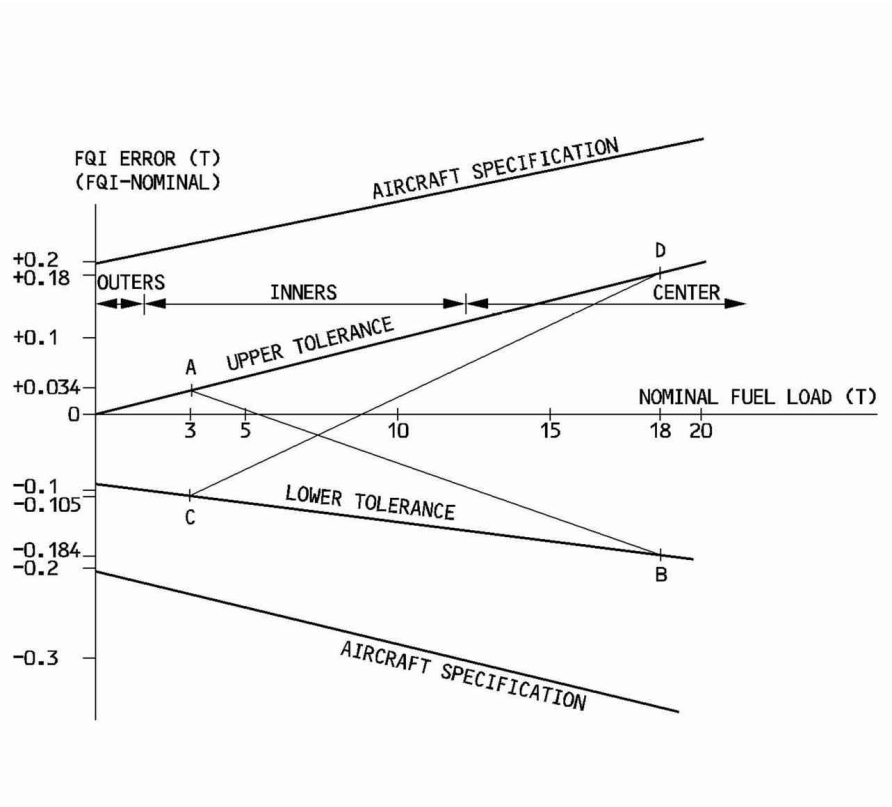
The accuracy of any measuring device such as the FQI system, is dependant on various parameters.
There are bias and random errors that can affect FQI system accuracy. Errors can involve tank manufacturing tolerances, FQI computer inaccuracies, error in density determination, probe-mounting tolerances, water that causes FQI over-reads, wing deflection, aircraft reference improperly taken into account.

The following figure gives, the Airbus Industrie standard specifications for FQI system accuracies on the A319/A320/A321:

- **Accuracy: ±** 1 % **of max tank capacity ±** 1 % **of actual fuel quantity**.
- Supplier:
  - A319/A320: Smiths and Intertechnique managed by **Smiths**
  - A321: BFE Goodrich and Sextant managed by **BFE Goodrich**.
- New probes compared to A310/A300-600
- Density sensors measuring all in-tank fuel as opposed to up-lifted fuel only for A310/A300-600
- Attitude correction from IRS in addition to fuel surface probe cutting.

Each aircraft is checked on ground prior to delivery to be within the tolerances shown on the following graphs (See Figure 1).
FAR/JAR 25.1337 requires that "each fuel quantity indicator is calibrated to read "zero" during level flight when the quantity of fuel remaining in the tank is equal to the unusable fuel supply..."
Tolerances are reduced when there is low level in the tanks in order to achieve an under-reading of the FQI as required by the regulations.

Figure 1



UNDERSTANDING FQI DISCREPANCIES

ON GROUND

Refueling personnel sometimes report discrepancies at the end of refueling, between the uplifted quantity based on FQI (total after refuel-total before refuel) and the uplifted quantity from the bowser (litres x measured density).

These discrepancies may be due to the following tolerance considerations.

Max discrepancy (Δ) = **Fuel load [per bowser] - Fuel added [FQI end - FQI start]**

= **±FQI error (end) ± FQI error (start) ± Bowser Qty and Density error + APU fuel burn** (during refueling)

Example (A320-200):
- Actual FOB before refueling = 3 t (6 600 lb)
- Actual FOB after refueling = 18 t (39 600 lb).

Bowser Quantity and Density Error

- Volume tolerance is generally lower than ± 0.5 %
- Density error due to both temperature accuracy and density reading: Δd = ± 0.002. Or ± 0.25 % on tolerance at any fuel loading.
  Total bowser quantity and density error = ± 15 000 x 0.75 % ~±115 kg (253 lb)

APU Fuel Used

- When comparing bowser data versus FQI data as indicated above, the reported discrepancy includes the fuel used by the APU between FQI readings before and after refueling.
- Depending on external conditions and generator load, the APU fuel consumption on ground is between 100 (220) and 150 kg/h (330 lb/h). For a refueling time of 30 min, APU burn would be at least 50 kg (110 lb).

FQI Errors

The three following cases should be considered:

1. Significant FQI system changes have been performed (FQI computer, probes change etc...) on the aircraft since delivery or its last FQI ground calibration.
   The FQI accuracy to be taken into consideration should be the one given by the aircraft specification i.e. ± 1 % of maximum tank capacity ± 1 % of actual fuel quantity.
   Assuming a maximum fuel capacity of 19 t (418 000 lb):
   FQI at start = 3 t ±220 kg (6 600 lb ±484 lb)
   FQI at end = 18 t ±370 kg (39 600 lb ±814 lb)
   Δ1 = ± 220 kg ±370 kg ±115 kg ±50 kg (Δ1 = ± 484 lb ±814 lb ±253 lb ±110 lb)
   Δ1 max ~ ± 755 kg **(**1 661 lb**)**
2. No FQI system modification has been performed since the last FQI calibration. All FQI readings are within the ground tolerances (See Figure 1).
   Maximum positive Δ is obtained when FQI presents the maximum over-reading at start and the maximum under-reading after refuel, i.e. when the particular aircraft calibration curve runs from A to B.
   Maximum positive Δ = 15.000 - [(18.000 - 185) - (3.000 + 35)] + 115 + 50 = + 385 kg
   Conversely, maximum negative Δ is obtained when particular aircraft calibration curve runs from C to D.
   Maximum negative Δ = 15.000 - [(18.000 + 180) - (3.000 - 105)] - 115 + 50 = - 350 kg
   Δ2 max ~ ± 385 kg (847 lb)
3. Particular aircraft FQI calibration curve is available.

In this case, although the reported discrepancy can be of the same magnitude as Δ2 maximum given above, after correction of FQI reading according to the calibration curve, the remaining difference should be due to bowser error and APU burn only.
Δ3 max ~ ± 165 kg (363 lb)

Conclusion

- When comparing bowser uplift versus FQI readings on ground, the maximum difference is: **Δ1 max = [FQI over-read (start)] - [FQI under-read(end)] + bowser error + APU burn**
- Difference can be significant when FQI over/underreadings before and after refueling are very different.
- An aircraft presenting a Δ ~ 0 does not confirm its FQI system is more accurate than another aircraft with a difference. It suggests (bowser error and APU burn not taken into account) that over/underreadings before and after refueling are very close but not necessarily equal to 0.

IN FLIGHT

As a routine, crews should check the fuel on board (FOB) plus fuel used (FU) against the block fuel during flight. This would detect fuel leaks and provide a more reliable basis of calculation in case of either FQI or FU failure during flight.
Discrepancies have been observed during routine checks.

These discrepancies are made up from the three following inherent errors:
- BLOCK FUEL (error constant throughout flight)
- FU (error increasing during flight)
- FOB (error decreasing during flight).

Example: A320 with 18 t
- BLOCK FUEL: 18 t →error = ± 370 kg (814 lb)
- FOB: 3 t →error = ± 220 kg (484 lb)
- FU: 15 t →error = ± 225 kg (495 lb)

In an extreme case:
Block Fuel = FOB + FU ± 815 kg (1 793 lb) **+ APU FU if any**
and this with no system fault.
Consequently, it is important to know the FQI tolerances to understand discrepancies.

Note: 1. *FU indication accuracy, which is an integration of the FF, is estimated to be better than ± 1.5 %. The error of the fuel flow (FF) meter is dependent upon fuel flow rate and temperature conditions. For normal cruise conditions, this error is around ± 1 %.*

2. *FQI errors for both Block Fuel and FOB are as per the specification because ground calibration curve is not applicable in flight. Block Fuel error, ground tolerances may be used if applicable (refer to 3.1). In this case, Block Fuel error is ± 185 kg (407 lb) instead of ± 370 kg (814 lb).*
   If the particular ground calibration curve is known, there should not be any substantial error on Block Fuel.
   Possible discrepancy due to FOB and FU errors remains significant:
   Block Fuel = FOB + FU ±** 450 kg (990 lb) **+ APU FU if any

3. *APU fuel used in flight, which is not recorded, is between 40 (88) and 100 kg/h (220 lb/h).*

4. *With the Flight Management and Guidance System (FMGS), FOB is also available on the appropriate page of the FMGS. FOB is computed by the FMGS using both FQI and FF data.*
   In the event of a FQI failure, the FMGS will continue to display FOB by means of the last available FOB and by FF integration.

USE OF MANUAL MAGNETIC INDICATORS

It often happens that when a discrepancy has been detected either on ground or in flight as explained above, some airline procedures request to make a check of the FOB after refueling or after landing by means of the Manual Magnetic Indicators (MMI).
It has to be highlighted that MMI readings involve several measurements and interpolations (on rods, on clinometers, on charts) in addition to the MMI indication accuracy itself.
This is why the accuracy of a MMI reading is approximately ± 5 % and thus worse than FQI system accuracy.
Therefore, MMI readings should not be used to check FQI system. They should only be used when the FQI system is inoperative.

REDUCING FQI DISCREPANCIES

FQI system accuracy continue to improve. Operational accuracy goals have been established by ARINC in cooperation with airframe and equipment manufacturers and in agreement with airline requirements.

The discrepancies described are inherent in the FQI system:

- Both on-ground and in-flight reported discrepancies are generaly due to FQI errors on Block Fuel.
  The Block Fuel maximum error should be reduced. This will depend on a responsible judgement based on knowledge of a particular aircraft FQI calibration curve; i.e. assuming no FQI modification following aircraft delivery, this curve will be reasonably constant (on ground) and thus, for a given FQI reading, real Block Fuel can be deduced.
  This calibration may be done by any operator while it is not applicable to the correction of in-flight reading.
  A FQI calibration procedure is a maintenance function and will be introduced in the AMM in the future.
- FU (fuel used) is the primary parameter to determine fuel consumption (max error = ± 1.5 %). Nevertheless, on certain high-fuel-capacity aircraft, the FOB error (decreasing during flight) may become lower than FU error (increasing during flight) by end of flight.
  Example: A320 with 19 t (41 800 lb) maximum capacity.

  • BLOCK FUEL = 18 t (39 600 lb)
  • FOB = 3 t ±1/100 (3 t + 19 t) = 3 t ±220 kg
    (FOB = 6 600 lb ±1/100 (6 600 lb + 41 800 lb) = 6 600 lb ±484 lb)
  • FU = 15 t x (± 1.5 %) = 15 t ±225 kg
    (FU = 3 300 lb x (± 1.5 %) = 3 300 ±495 lb)

In this example, when FOB is less than 3 t (6 600 lb), FOB error may be assumed to be lower than FU error. Furthermore:

- If Block Fuel is confirmed as per a particular calibration curve:
  • When FOB >3 t (6 600 lb):
    Use FU parameter to determine both FOB and FU
  • When FOB <3 t (6 600 lb):
    Use FOB parameter to determine both FOB and FU

OPERATIONAL CONSIDERATIONS

Some economic aspects relating to FQI accuracy are approached here and should be considered when operating an aircraft.

TECHNICAL DELAYS

Incorrect application of MMI check, may cause a possible delay.
Knowing the FQI calibration curve helps to understand and reduce discrepancies.

EXTRA FUEL LOADED

- Crews uplift more fuel than required for a particular flight, as a contingency factor, when they are unsure of the FQI accuracy.
- An under-reading FQI leads also to carrying extra fuel.
- 1 extra tonne will increase fuel consumption up to 1.2 %, depending on airframe and flight conditions.

PAYLOAD PENALTY

Extra fuel loaded due to uncertainty of FQI may lead to decreasing the payload.

Payload = TOW + TAXI fuel - OEW - Fuel loaded

TOW = Take-Off Weight

OEW = Operating Empty Weight

We have seen, that adding 130 kg (286 lb) of fuel can allow the payload to be increased by 870 kg (1 914 lb) on a 4 h flight.

- When the payload is **limited by MTOW** as TOW cannot be increased, **any extra fuel will decrease** and replace payload by the **same amount**.
  Also, **any defueling will significantly decrease the payload.**
- When the payload is limited by the max fuel capacity:
  - If the FQI under-reads, the payload could be increased
  - If the FQI over-reads, the payload should be decreased.

For example, an inaccuracy of ± 130 kg (286 lb) on fuel can affect the payload by ± 870 kg(1 914 lb).
Again, knowing your FQI calibration curve allows to adjust the payload.

Note: Although not approved by DGAC/JAA as it is a non compliance item, using the 2 % thermal expansion volume as extra-fuel could be authorized by national airworthiness authorities to increase max fuel capacity.
In this case the FQI reading is limited somewhere above high level until fuel quantity falls below this value.

CONCLUSION

Airbus Industrie has always improved FQI systems, because it is essential for crews to have a reliable and accurate fuel quantity indication system.
Taking into account the difficulty of measuring the weight of a liquid stored in complex-shaped tanks always moving, FQI system installed on Airbus aircraft has a good accuracy, well within specifications and international standards.
It is important on certain flights with certain aircraft fitted with a FQI system presenting large over-/underreadings, to know the particular FQI ground calibration curve.

Crews should know this curve and FQI tolerances in order to:

- Understand and reduce FQI discrepancies
- Avoid delays
- Save fuel
- Adjust the payload.

FQI calibration should be done when deemed necessary by each operator as this will be profitable for both operational and economic aspects.

ELECTRONIC INTERFERENCE FROM PORTABLE EQUIPMENT CARRIED ON BY PASSENGERS

Intentionally left blank

FCB-FCB8-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Electronic Interference from Portable Equipment carried on by Passengers.....A

Intentionally left blank

ELECTRONIC INTERFERENCE FROM PORTABLE EQUIPMENT CARRIED ON BY PASSENGERS

Applicable to: ALL

- Airlines often wonder whether they should allow passengers to operate electronic devices in the cabin without any limit.

  Federal Aviation Regulation (FAR) section 91.19 allows passengers to operate:
  - Portable voice recorders
  - Hearing aids
  - Heart pacemakers
  - Electric shavers
  - Any other portable electronic device that the operator of the aircraft has determined will not cause interference with the navigation or communication system of the aircraft on which it is to be used.

  It is obvious that the myriad portable devices that now exists or that may be available in the future cannot be tested.
- As far as aircraft specific electrical flight controls and engine control computers on Airbus aircraft are concerned, there is no chance of their operation being affected by passenger-operated electronic devices, due to the high level of protection applied to these systems.
- Nevertheless, this question arises for navigation and communication receivers and is applicable to any aircraft.
  A study has been conducted by an RTCA (Radio Technical Commission for Aeronautics) special commitee.
- The conclusion is that the probability of a passenger-operated device interfering with the ILS localizer during a typical flight is about one in a million.
  Airbus Industrie recommendations is that no portable device should be used during take-off and landing.
- Concerning radio phones Airbus Industrie recommends to prohibit the use of those devices.

FLIGHT CREW BULLETINS

THRUST ACCELERATION IN A/THR MODES

Intentionally left blank

FCB-FCB9-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Thrust Acceleration in A/THR Modes.....A

Intentionally left blank

THRUST ACCELERATION IN A/THR MODES

Applicable to: ALL

These are specific thrust acceleration logics when A/THR is engaged in thrust or speed mode. The crew should be aware of each.
The purpose of the logic is to obtain adapted thrust variation to the whole flight envelope, depending on the current mode engaged, "G" load limitation, and vertical modes switching if any.
This is based on different logics which can be summarized as following.

1. LOGIC IN THRUST MODE "CLB"(ASSOCIATED WITH OP CLB/EXP CLB/CLB)

1.1 WHEN AP IS ENGAGED

During thrust increased, the maximum acceleration rate is 20 %/sec until the N1 reaches N1 target minus 5 %. At that point, the acceleration logic is speed mode. This acceleration limit is defined to achieve a smooth and rapid transition without noticeable speed excursion.
However normal acceleration rate is between 1.5 %/sec and 20 %/sec.
When target N1 minus 5 % is reached, N1 rate becomes 1.5 %/sec until target N1 (MAX CLB Thrust) is obtained.

Note: When decelerating (more than 10 kt between current speed and speed target), the N1 rate is maintained at 1.5 %/sec.

1.2 WHEN AP IS OFF

It has been revealed, that during manual flying with AP off, the rate limit up to 20 %/sec was not as optimum as with AP engaged. The reason for this is that during transition the system was using A/THR speed mode logic to obtain N1 rate limit of 20 %/sec MAX; if the pilot did not fly the FD bars, established CLB thrust was not always obtained.
Consequently, the current system maintains the fixed value of 1.5 %/sec which represents the best value when following the FD bars.
Flight tests proved this logic (it means to provide maximum rate of 20 %/sec only if autopilot is engaged) to be the optimum compromise through the flight envelope.

WARNING	If FD bar commands are not smoothly followed or not followed at all, a speed excursion may occur, due to the fact that the change of attitude is not adapted to the thrust acceleration rate. If required, additional manual thrust may be briefly added by the pilot during the transition.

2. LOGIC IN THRUST MODE "IDLE" (ASSOCIATED WITH OP DES/EXP DES/DES)

The N1 rate limit is 2 %/sec (IS8) and 1 %/sec (full standard). Both rates were selected to preclude speed excursion and improve passenger comfort (smooth attitude variation during transition).

3. LOGIC IN SPEED MODE

The N1 rate limit is 20 %/sec MAX, however it can be lower depending upon the difference between the current speed and the target speed.
There is no difference in A/THR speed mode linked to AP ON or OFF. The speed hold is the same with AP ON or OFF.
When pilot is flying manually, a temporary speed loss can occur if an increased load factor is required. This authority is not possible with AP due to system.

FLIGHT CREW BULLETINS

RADIO ALTIMETER ANOMALIES DURING ADVERSE WEATHER CONDITIONS

Intentionally left blank

FCB-FCB11-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Radio Altimeter Anomalies during Adverse Weather Conditions..... A

Intentionally left blank

RADIO ALTIMETER ANOMALIES DURING ADVERSE WEATHER CONDITIONS

Applicable to: ALL

INTRODUCTION

All radio altimeters are very sensitive to adverse weather conditions.
Reflections from hail clouds or heavy precipitation located between the ground and the aircraft, may cause the radio altimeter to indicate a false height value momentarily.
These erroneous indications are also transmitted to other systems which may induce spurious warnings or unexpected AP/FD guidance.

EXAMPLE	Under heavy rain condition at 2 600 ft, at least one of the radio altimeter delivered a height indication of 480 ft during 13 s. The warning "L/G gear not down" was displayed. No other anomaly was reported until landing.

EXPLANATION

ORIGIN

A radio altimeter measures the shortest distance between the aircraft and the closest obstacles below it.
During adverse weather conditions, returns can be generated due to reflection on hail clouds or heavy rain. The energy which is reflected depends directly upon the hail or rain density.
If the energy received by the radio altimeter is powerful enough, it will be validated and a height lower than the distance to the ground will be measured and sent to system users.
If the return is too weak, the measurement will be validated but the increased noise level may hide the return from the ground and thus no height indication would be provided.

CHARACTERISTICS

This phenomenon is rare. Typical weather conditions which trigger these effects are not frequent and generally isolated.
It is less likely with increased height.
Due to the physical nature of the hail and rain and the radio altimeter characteristics, the radio altimeter indication will only be influenced if the distance between the A/C and the clouds is equal or greater than 300 ft for rain and 80 ft for hail.
Both radio altimeters are likely to be affected simultaneously.

OPERATIONAL CONSIDERATIONS

If both radio altimeters are affected simultaneously the crew may experience:

- If the value is greater than 150 ft:
  - Spurious auto call out
  - Spurious ECAM or GPWS warnings.
- If the value ranges between 150 ft and 80 ft:
  - During automatic approach:
    - Degradation of the guidance, glide slope is no longer flown, excessive deviation may occur
    - Variation of the longitudinal pitch and/or vertical speed leading to GPWS warning.
  - During manual approach:
    - No adverse effect could be reproduced during simulation but GPWS or auto call out warning might be spuriously triggered.

CONCLUSION AND OPERATIONAL RECOMMENDATIONS

Very few cases of spurious radio altimeter indications have been reported to Airbus. Radio altimeter sensitivity issues have been tuned to the limits of improvement. There is no practical solution to cure the phenomenon without reducing system performance to an unsatisfactory level. Crews need to be aware that erroneous radio altimeter behavior is rare, but can occur during severe weather conditions. During approach and landing, crews need to consider this phenomenon.

The weather radar may be used to detect heavy rain or hail.

The interpretation of the color codes is as follows:

Black rainfall rate	less than	0.7 mm/hr
Green rainfall rate	between	0.7 and 4 mm/hr
Yellow rainfall rate	between	4 and 12 mm/hr
Red rainfall rate	greater than	12 mm/hr

As an example stormy tropical shower rate can be as high as 500 mm/hr and uppest limit for hail may reach 4700 mm/hr.

FLIGHT CREW BULLETINS

FMGS NAVIGATION DATA BASE

Intentionally left blank

FCB-FCB12-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

FMGS Navigation Data Base..... A

Intentionally left blank

FMGS NAVIGATION DATA BASE

Applicable to: ALL

REASON FOR ISSUE AND SCOPE

The aim of this FCOM Bulletin is to highlight the importance of the Navigation Data Base accuracy and therefore the importance of its update and its correctness.
As any NAV data base discrepancy or false coding may induce navigation errors and lateral or vertical misguidances, this FCOM Bulletin provides flight crews with operational recommendations.

INCORRECT NAV DATA BASE CASES

NAVIGATION DATA BASE DISCREPANCIES

Numerous in service events have been reported during the last few years, which are caused by 3 different types of Navigation Data Base discrepancies:

- NAV data base not updated on time
- Incorrect coding or impossibility of coding of published procedures
- Coding errors.

NAV Data Base Not Updated on Time

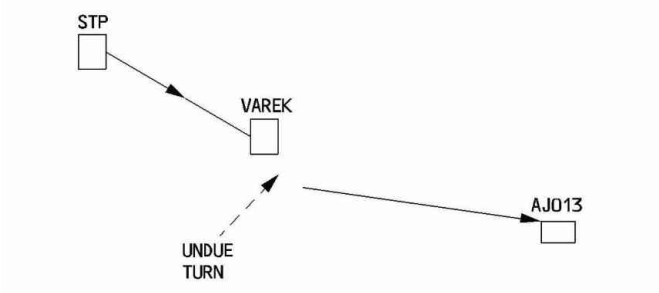
When a NAV Data Base is not updated on time, this may lead to incorrect position or misguidance:

- 1st example
  STAR MEN2 (LFBO) was modified but not incorporated in the NAV D.B. As a result the STAR displayed on the ND was not the published one.
- 2nd example
  TRANS between STAR VAREK and NDB03 was not coded at Ajaccio (LFKJ). Misguidance was the consequence.

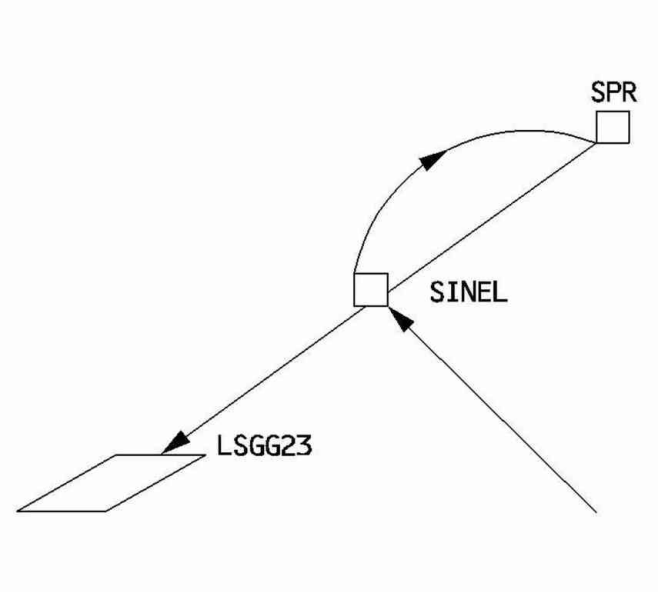
NAV Data Base Incorrect Coding

Incorrect coding in the NAV D.B. induces misguidance in SID or STAR:

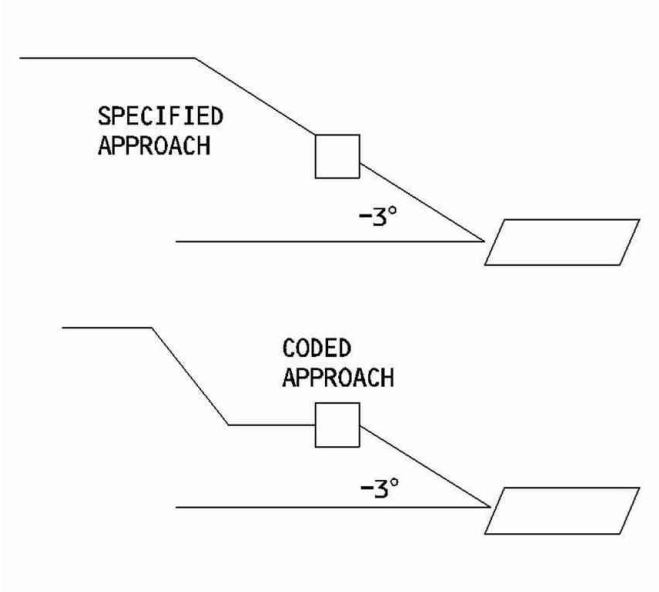
- 1st example
  STAR VAREK at Ajaccio (LFKJ).
  The leg STP-VAREK was coded as a TF (track to fix) and the following leg was coded as a CF (course to fix). Due to the imprecision of the magnetic variation in the area, both legs were not lined up and the A/C had to turn, after VAREK WPT, to capture the next leg.



- 2nd example
  STAR PERIK 1 and GORON 1 AT Genova (LSGG).
  These STARs end at WPT SINEL located in the middle of the APPR 23.
  This creates a F-PLN discontinuity and the procedure is not flyable. The NAV D.B. error is linked to both coding and procedure concept.



- 3rd example
  On several non precision approaches, the final descent angle is coded for the last leg only instead of the last 2 legs. Again this creates a level off segment which does not exist.



Coding Errors

Coding errors generally have very similar effects on the FMGS system and may induce position errors as well as misguidance:

- 1st example
  Erroneous position of runway threshold at LFMT RWY 32R inducing a lateral offset during non precision approach
- 2nd example
  ILS/DME coded as an ILS only preventing autotuning of the DME in approach (IWW and IGG at EGKK).

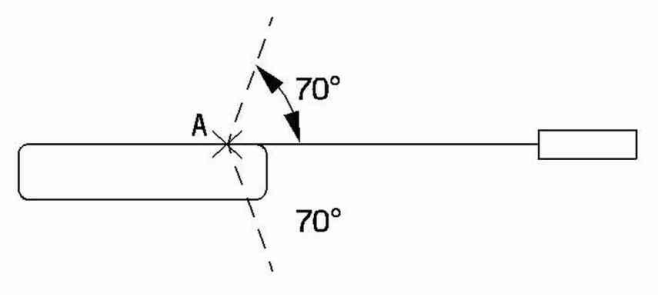
PROBLEMS LINKED TO ARINC 424 SPECIFICATION

If an item is not specified in the ARINC 424, it will not be part of the NAV D.B.
For example:
No specific field reserved for THR RED/ACC ALT. As a result, it is not possible to link such information to a company route (e.g noise abatement). Defaulted value is provided instead.

Systematic Coding of HF Leg in Procedures

When a Final Approach procedure displays a Holding Pattern, this pattern is systematically coded in the APPR VIA or STAR as an HF leg; this means that this holding is always taken

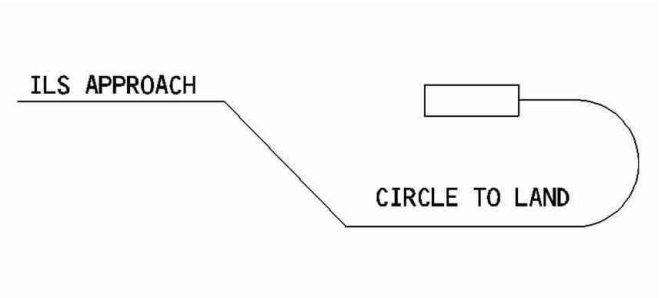
into account in the F-PLN, assuming one turn; in certain cases, this is realistic but in most circumstances, it is not.



If the HF leg is of no use, it corrupts all predictions and performance computations.
Furthermore if a holding pattern is ATC required, by then the crew has all means to insert it into the F-PLN, and be then provided with realistic estimates.
As a consequence, realistic coding of procedure turns should be requested.

Circle to Land

At many airports approaches are defined only in one direction; while the landing runway may be in the other direction.
If the weather is poor, a defined instrument approach is carried out down to circle to land MDA, and then a circle to land trajectory is flown.
Circle to Land feature is not part of current ARINC specification; this forces the crews to improvise in order to get a realistic trajectory on the ND, and to get proper predictions on CDU



RECOMMENDATIONS

In order to control and correct NAVIGATION Data Base all pilots are encouraged to report to their flight operations any misbehaviour which may have been induced by an incorrect data base.

This can be done during normal operations:

- During preflight by checking the consistency of the MCDU F-PLN versus ATC F-PLN. Refer to current FCOM
- In flight by performing the navigation accuracy assessment on a regular basis as described in the FCOM procedures and techniques.

CONCLUSION

Tomorrow, the increasing number of RNAV approaches will require faultless NAV Data Base procedures since it will not always be possible to monitor the guidance by using raw data.
On a short term basis, the NAV Data Base improvement is a matter of step by step error detection which mainly requires pilot attention during preflight and in flight.
On a longer term basis, the NAV Data Base improvement requires decisions and actions of concerned agencies/authorities and NAV Data Base manufacturers.
It has to be reminded that the aircraft constructor has no control over the data base used by each operator.

FLIGHT CREW BULLETINS

SPECIFIC FEATURES OF THE FMGS
FULL STANDARD

Intentionally left blank

FCB-FCB13-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Specific Features of the FMGS Full Standard..... A

Intentionally left blank

SPECIFIC FEATURES OF THE FMGS FULL STANDARD

Applicable to: ALL

Note: This FCOM bulletin is only valid for aircraft equipped with FMGS full standard.

The FMGS full standard was introduced in 1992. During the first months of service, questions have been raised on particularities of the system.

1. ALTITUDE PREDICTIONS NOT ACCURATE ON GROUND

Predicted altitudes indicated on the F-PLN A page are not accurate until take off; an error of a few hundred feet may be noticed on predicted altitudes at all waypoints until lift off.

EXPLANATION

The predictions are computed using simplified model for the take off run. This causes a minor error on the altitude predictions. Predictions are continuously updated during the take off roll and once airborne, they are accurate.

2. SPURIOUS "FMS 1/FMS 2 SPD TGT DIFF" MSG

When changing of CRZ FL using the FCU altitude knob, the message "FMS 1/FMS 2 SPD TGT DIFF" may come up.

EXPLANATION

The new FCU altitude is sent by the master FMGC to the slave, therefore predictions are not computed at the same time on both FMGCs; a speed target difference may occur during a very short period, triggering the message.

PROCEDURE

Disregard the message.

3. "IRS ONLY NAVIGATION" MSG TRIGGERED AT DESCENT PHASE SWITCHING

When the A/C is in IRS ONLY NAV mode, the message "IRS ONLY NAVIGATION" is triggered when the A/C starts the descent.

EXPLANATION

The system logic is triggered when the FMGS navigation mode has been in inertial only for more than 10 min in cruise or when the A/C is transitionning to descent phase without radio updating.
If the FMGS is in IRS only navigation mode at descent phase switching, the message is immediately triggered, reminding the crew that the A/C is operating without radio position.

PROCEDURE

Perform a NAV ACCY CHECK.

4. VERTICAL DEVIATION DIFFERENT ON BOTH SIDES

In descent or approach the vertical deviation (VDEV) indicated on the PFD and PROG page may differ on side 1 and 2.

EXPLANATION

The vertical deviation (VDEV) is computed independently on side 1 and 2; if FM 1/2 position ground speed or other data used for VDEV computation differ slightly from side 1 and 2, a small difference of VDEV will be observed during descent and/or approach.

5. INCREASE OF VERTICAL SPEED IN DES MODE

The vertical speed may increase noticeably for a short period of time during descent with DES mode engaged. The V/S regains the normal value when intercepting the path.

EXPLANATION

When the A/C is above path and an increase of speed target is required manually or automatically, the V/S will increase temporarily until the vertical profile is intercepted.

6. VLS COMPUTATION

6.1 The VLS computed by the FMGS uses the same algorithm and performance table as the FAC. Nevertheless some differences may be observed due to the fact that the FAC computes the VLS from flight parameters and the precision of the computation provides an accuracy of ±3 kt (PFD VLS).

6.2 In CONF 3, the performance table used to compute the VLS assumes the gear up although the table provided in the QRH and FCOM assume gear down. A VLS difference of 2 kt can be observed between performance table and FAC/FMGS in CONF 3.

7. A/C POSITION INVALID

When a fast realignment is performed, the message A/C POSITION INVALID is triggered.
The message disappears when the realignment is completed.

EXPLANATION

During an IRS alignment, the ADIRS send no data to the FMGS and the FMGS cannot process any position.
The POS MONITOR page is empty and the MSG "A/C POSITION INVALID" is automatically triggered. Once the IRS are realigned, the ADIRS provide data to the FM and a mix IRS position is recomputed; the message disappears.

FLIGHT CREW BULLETINS

VMO/MMO DETERMINATION

Intentionally left blank

FCB-FCB15-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

VMO/MMO Determination.....A

Intentionally left blank

VMO/MMO DETERMINATION

Applicable to: ALL

GENERAL

VMO (the design cruising speed) is the maximum operating speed that the crew may fly within the normal flight envelope. It is not authorized to fly intentionally above this limit.
VD is the design dive speed. VMO and VD must comply with load requirements (gust loads, maneuvering loads). For example, the aircraft must be able to sustain a load factor of 2.5 up to VD. The range between VMO/VD considers normal reaction time to the crew to use standard recovery techniques for returning the aircraft to normal attitude at a speed of VMO/MMO.
The A319/A320/A321 are protected by the High Speed Protection law which automatically makes the recovery if VMO is exceeded (between VMO and VMO +6) as shown in the following table.

HIGH SPEED/MACH TABLE

MD = 0.89	VD = 381 kt	VD = VMO +31 kt
MMO +0.04	VMO +20 kt	Structural inspection required. (Refer to relevant AMM section)
MMO +0.01	VMO +6 kt	Upper limit for entry into HSP
MMO +0.006	VMO +4 kt	Overspeed warning
MMO = 0.82	VMO = 350 kt	Max operating SPEED/MACH and lower limit for entry into HSP
MMO -0.006	VMO -3 kt	Max upper speed range in DES mode.
MMO -0.02	VMO -10 kt	Managed speed target limit (ECON mode)

Depending upon the speed trend, the autopilot will disconnect at or below VMO +6 kt/MMO +0.01 and an automatic pitching up will allow VMO to be regained.
Per design, in DES mode or OP DES mode, autopilot authority is limited to 0.1 g compared to 0.15 g in EXPEDITE. This limitation was required by the launching customers for passenger's comfort.
Due to the load factor limitation, some flight paths or environment conditions depending on their magnitude, may not be counteracted by the autopilot leading to VMO/MMO overshoot.
A short exceedance of few knots above VMO has no consequences on the aircraft.

Nevertheless, an intentional exceedance is not authorized:
- By regulation
- Because above VMO/MMO the HSP (high speed protection) may be activated automatically. Any pilot input to recover the target speed may be added to the HSP order, leading to a load factor incompatible with passenger's comfort.

For this reason, it is recommended to be smooth on the stick when manually recovering from a VMO/MMO exceedance. In order to prevent this exceedance during descent, a procedure has been described in *Refer to PRO-NOR-SRP-01-60 Descent Initiation*.

FLIGHT CREW BULLETINS

OPERATION OF FLEETS WITH/WITHOUT CPIP

Intentionally left blank

FCB-FCB16-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Operation of Fleets with/without CPIP..... A

Intentionally left blank

OPERATION OF FLEETS WITH/WITHOUT CPIP

Applicable to: ALL

INTRODUCTION

In order to continuously improve the man/machine interface, Airbus developed continuous product improvement programmes (CPIP), the modifications of which are available for retrofit and are commonly introduced on all new A320/A321 and on A319.
This FCOM bulletin details the differences which crews should be aware of.

DEFINITION

BASIC AIRCRAFT

The A320 equipped with full standard FMGS without CPIP (continuous production improvement programme) nor ENERGY MANAGEMENT.

ADVANCED STANDARD

The A319/A320/A321 with CPIP 1 + 2 + 3, LOW ENERGY warning and ENERGY MANAGEMENT. This standard is basic on the A319/A321 and A320 in current production and can be retrofitted to all A320.

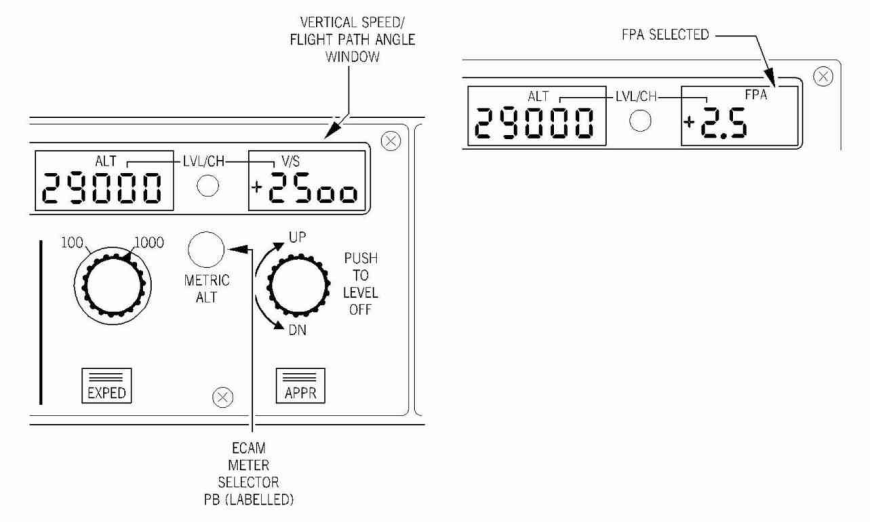
MODIFICATION DESCRIPTION

CPIP 1 (FCU MODIFICATION)

- Altitude selection change inhibited during push/pull action. This modification prevents any change of altitude during mode engagement.
- HDG and V/S preselection time increased from 10 to 45 s.
- V/S/FPA click differentiation for rapid selection:
  1 click = 1 ° FPA
  2 clicks = 100 ft/min V/S

CPIP 2 (FCU MODIFICATION)

- V/S/FPA "push to level off" function.
  When pushing the V/S/FPA selector knob, V/S/FPA target is set to zero.
- 4 digits for V/S target.
  The V/S and FPA target are displayed in the window as followed:
  V/S = 4 digits
  FPA = 2 digits
- HDG/TRK target is synchronized when switching from HDG to TRK or vice versa.
- SPD/MACH, HDG/TRK, METRIC ALT switching pushbuttons are labelled.

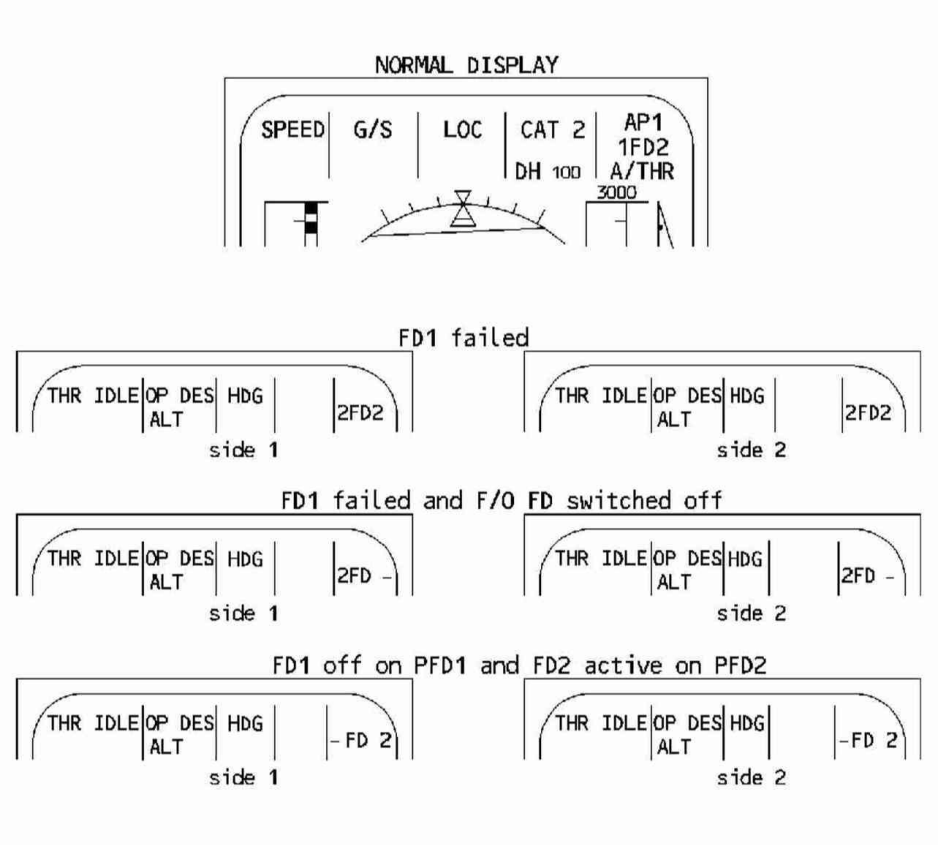


LOW ENERGY WARNING (FAC AND FWC MODIFICATION)

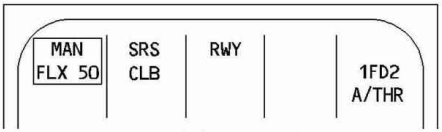
The low energy warning consists of an aural warning "speed speed speed" triggered every 5 s. This warning is available when CONF ≥2 and 100 ft <RA <2 000 ft; it indicates that the energy level is not sufficient to recover to a positive flight path angle with only pitch command. The thrust must be increased. This warning is generated before the alpha floor is triggered.

CPIP 3: FMA IMPROVEMENTS (DMC AND FWC MODIFICATION)

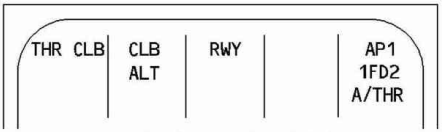
- Engagement status of both FDs are displayed on both PFDs:



- A/THR annunciations are changed as follows:
  - White colour and MAN label when the thrust levers are set manually in the corresponding detent. e.g. MAN TOGA, MAN FLEX, MAN MCT.
    MAN THR when the thrust levers are set above the applicable detent. The A/THR is armed (A/THR blue on FMA).
  - LVR white (or amber) label whenever the thrust levers are not in the correct detent: (e.g. LVR CLB, LVR MCT, LVR ASYM)
  - THR green label when the Thrust mode is active:
    THR CLB, THR MCT, THR IDLE.

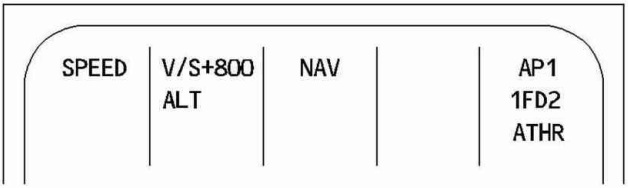


Typical FMA with RWY mode engaged



Typical FMA in climb

- All AP/FD modes are displayed as abbreviations (no dashes): (e.g. NAV, ALT CRZ, ALT CSTR).
- V/S or FPA target are displayed in the FMA: e.g. V/S: + 800
- Message and MSG colours are changed as follows:
  "MORE DRAG" white message instead of "AIRBRAKES"
  "CHECK APP SEL" white message instead of "CHECK APP GUIDANCE"
  "SET MANAGED SPD"white message instead of "SET AUTO SPEED"
  "SET GREEN DOT SPD"white message instead of "SET VFTO"



ENERGY MANAGEMENT IMPROVEMENT

(FAC, FWC, DMC, FADEC modification)

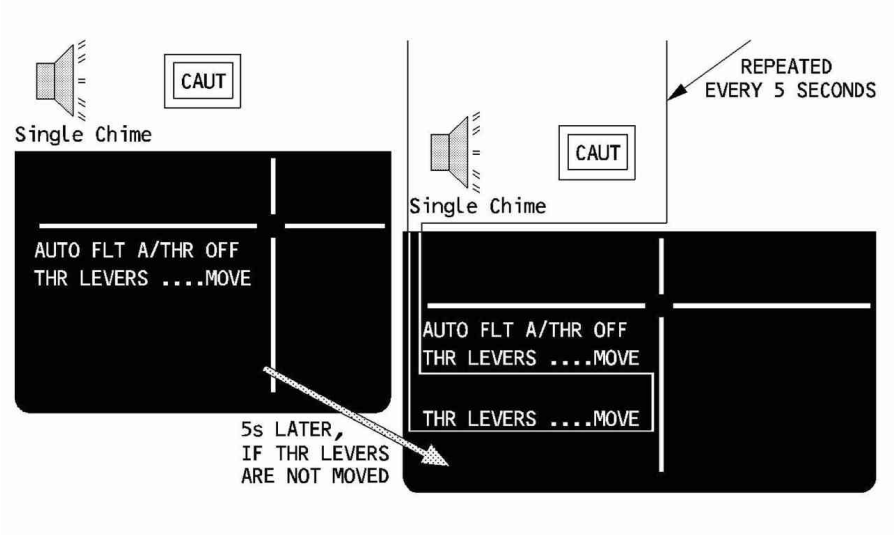
The ENERGY MANAGEMENT package is related to A/THR logic modification and additional ECAM announcements. The package eases the normal procedure of A/THR disconnection and improves the crew information on the current thrust setting.

A/THR Disconnection Using the Instinctive Disconnect Pushbutton

When the instinctive disconnect pushbutton is depressed:

- Thrust is immediately set to the thrust corresponding to the thrust lever position. (Thrust lock no longer effective)
- A gong sounds and the master CAUTION light illuminates for 3 s
- AUTO FLT A/THR OFF is displayed on the ECAM for 9 s maximum.

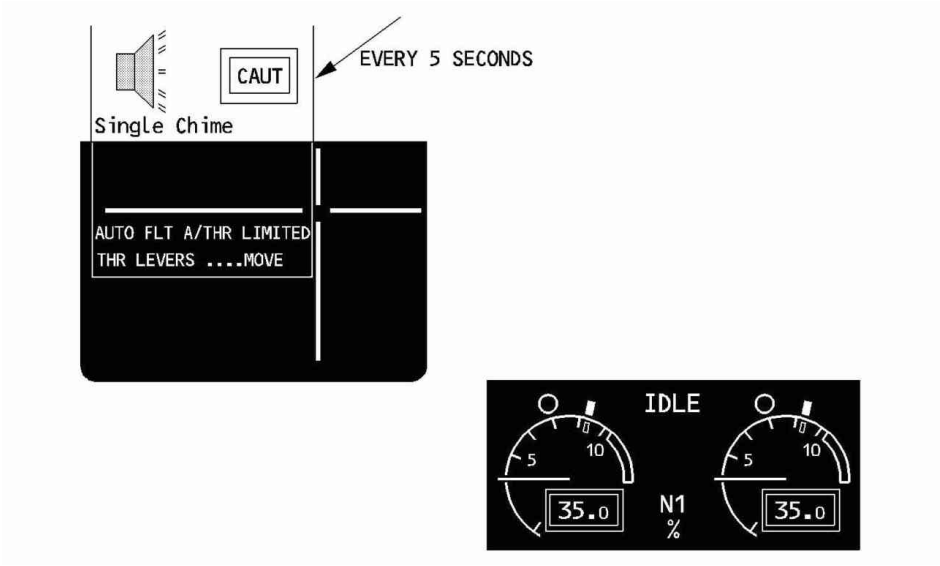
A/THR disconnection due to a failure or an action on the A/THR FCU P/B when illuminated green:



- THRUST LOCK is active until the thrust levers are moved out of corresponding detent (or alpha floor activates)
- Annunciation is enhanced as follows:
  - Repetitive gong and master CAUTION light
  - THR LK amber displayed on both PFDs
  - AUTO FLT A/THR OFF displayed on ECAM
  - Blue "THR LEVERS.....MOVE" displayed on ECAM
  - With a 5 s delay, flashing "ENG THRUST LOCKED".

Thrust levers set below CL detent:

- Repetitive gong and master CAUTION light
- "AUTO FLT A/THR LIMITED" and "THR LEVER...MOVE" displayed on ECAM
- LVR CLB displayed on FMA



IDLE announcement on ECAM

When thrust is set automatically or manually at IDLE thrust, IDLE legend flashes green for 10 s then steady on ECAM EWD (adjacent to N1/EPR scale).

OPERATIONAL CONSIDERATIONS

FCU MODIFICATION (CPIP 1 AND CPIP 2)

The introduction of FCU modifications does not significantly modify the published procedures:

- V/S push to level off function
  V/S = 0.0 selection may still apply; the "push to level off" function is a easier action. In both cases, the crew must crosscheck with FMA.
- Different digits for V/S and FPA
  The procedure which consists of crosschecking (and announcing) V/S or FPA value obtained on PFD remains mandatory.
- Synchronisation of HDG/TRK target
  This allows the switching from HDG to TRK or vice versa with bank angle.
  Airbus still recommends the switching with wings level.

LOW ENERGY WARNING

This feature provides an advanced warning to the crew before alpha floor is triggered.
Standard procedures are unchanged and flight envelope remains the same.
Alpha floor and alpha protection are identical.

CPIP 3

The announciations of the FMA are self explanatory.

The procedure remains the same:

- Any mode change is to be checked and announced.
- When a new target is selected and activated through the FCU, the resulting guidance has to be checked on the PFD.

ENERGY MANAGEMENT

The main feature of the ENERGY management is the suppression of the thrust lock when the A/THR instinctive disconnect pushbutton is used.
The A/THR disconnection technique remains unchanged (*Refer to PRO-SUP-70 Thrust Control*), and may be summarized as follows:

When A/THR is to be disconnected:

- Move the thrust levers out of the applicable detent, to the current or desired thrust level
- Depress the instinctive disconnected pb.

The new ECAM features facilitate the crew action but do not modify the procedures.

FLIGHT CREW BULLETINS

CHARACTERISTIC AND PROTECTION SPEEDS

Intentionally left blank

FCB-FCB17-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Characteristic and Protection Speeds..... A

Intentionally left blank

CHARACTERISTIC AND PROTECTION SPEEDS

Applicable to: ALL

INTRODUCTION

The different speeds displayed to the crew on the main cockpit interfaces: PFD, MCDU, ND are computed by the FACs, the FMGCs and the ADIRS.

PFD	MCDU PERF PAGE
FAC COMPUTATION Computed on current aircraft status and configuration.	FMGC COMPUTATION Computed for take off, go around and landing.
VLS F S "O" Green Dot Vαprot Vαmax Vsw (stall warning speed)	VLS of the selected landing configuration. F S "O" Green Dot

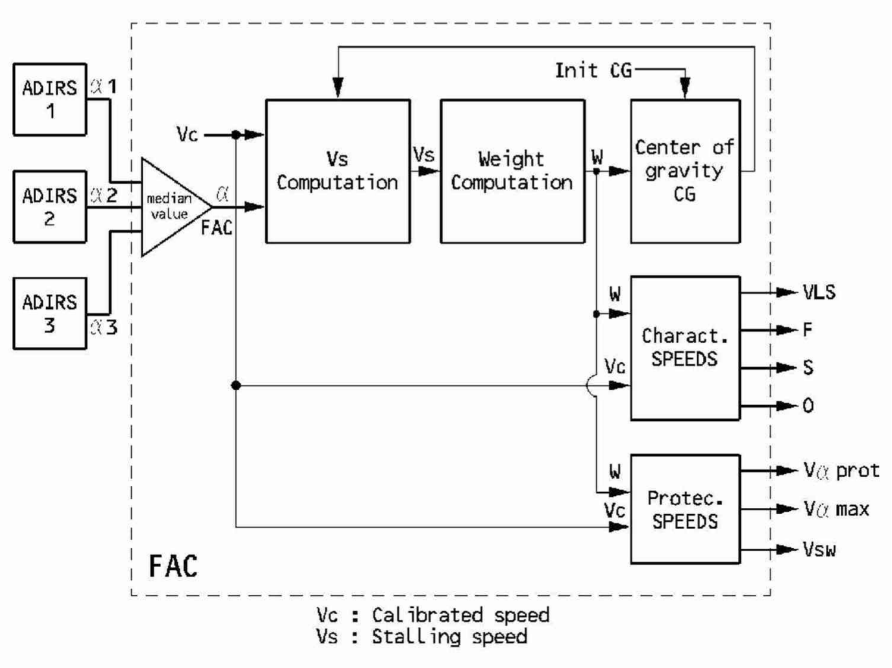
Each FAC computes its own speeds which are displayed on the relevant PFD:
FAC 1 on side 1
FAC 2 on side 2.

Each FMGC computes its own speeds displayed on the relevant MCDU:
FMGC 1 on side 1
FMGC 2 on side 2.

The algorithms used to compute the characteristic speeds are the same in both FAC and FMGC but as the inputs are different, the resulting values may differ.

CHARACTERISTICS SPEEDS COMPUTED BY THE FAC

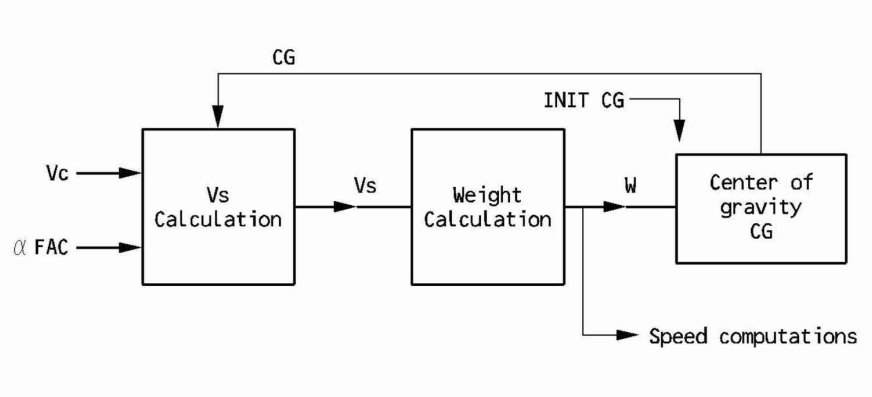
The FAC computes its characteristic speeds with 2 main inputs from ADIRS (Angle of Attack (α) and calibrated airspeed (Vc)). It also uses THS position, SFCC data and FADEC data.
From these inputs, the FAC computes a stall speed Vs which is used to determine the aircraft weight.
The following sketch gives the basic architecture for FAC speed computation.



AOA DETERMINATION

The angle of attack value used to compute the characteristic speeds is the mean value of the 3 AOAs (Vote).
Accuracy of the AOAs is a paramount factor in the weight calculation.
0.3 ° of error in the AOA results in a 3 t error in weight.

WEIGHT COMPUTATION



The weight is computed provided the following conditions are met:
- Aircraft altitude below 14 600 ft and speed (Vc) below 240 kt
- Bank angle less than 5 °
- Speedbrakes retracted
- No dynamic maneuver (vertical load factor lower than 1.07 g)
- No change of aircraft configuration and not in CONF full.

When one of these conditions is not met, the last calculated weight value is considered and updated for the fuel consumption based on actual engine N1.

CHARACTERISTIC SPEEDS COMPUTATION

A320

VLS is computed from Weight and Vc and corrected for the current CG.

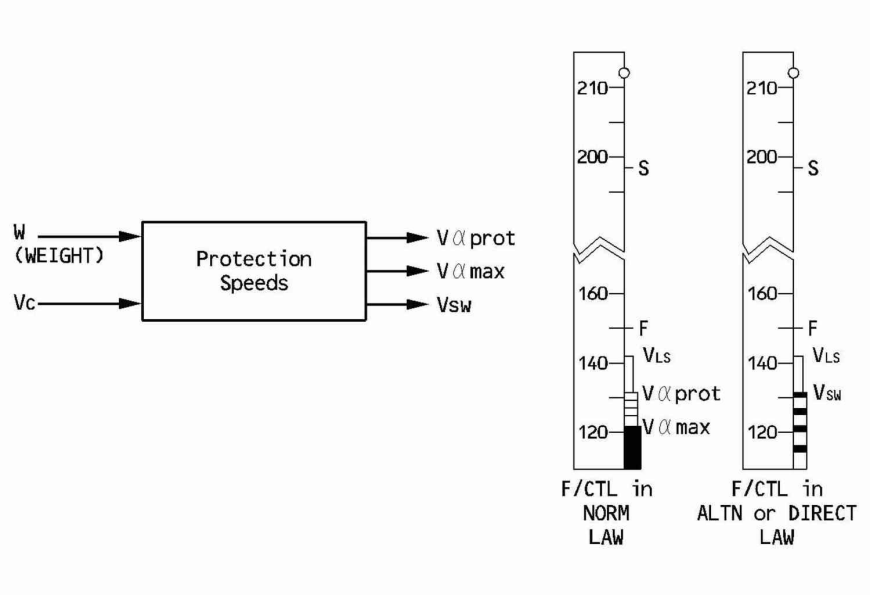
- If the current CG is forward of 15 %, 15 % CG is used to compute the speeds
- If the current CG is between 15 % and 25 %, the speeds are computed using an interpolation between 15 % and 25 % CG
- If the current CG is aft of 25 %, 25 % CG is used for speed computation.
  F, S, and Green dot are independent of CG.

A319-321

VLS, F, S and Green Dot are computed for a forward CG. No CG correction is applied for A319/A320 VLS as it has a negligible effect.

PROTECTION SPEEDS CALCULATED BY THE FAC

Vαprot and Vαmax are displayed in normal law.
The FAC does not trigger alpha prot and alpha MAX protection.
(The alpha prot and alpha max protection are activated by the ELAC).
Vsw, the stall warning speed is computed by the FAC in ALTN or DIRECT law. At Vsw speed, an audio warning (crickets - STALL synthetic voice) is triggered.



TOLERANCE OF FAC COMPUTED SPEEDS

Due to the data accuracy used to compute the characteristic speeds, and specifically the AOA accuracy, the precision of the computation is specified to be within 2.5 %.

During acceptance flight, the tolerances are as following:

Clean aircraft

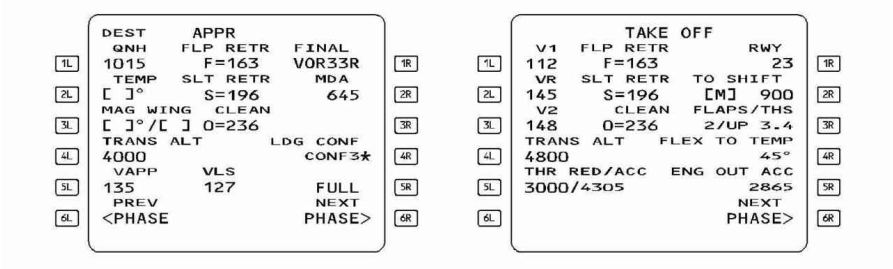
Green Dot	±5 kt
VLS	±4 kt
Vαprot	±5 kt
Vαmax	±5 kt

Conf full

VLS	±3 kt
Vαprot	±5 kt
Vαmax	±5 kt

CHARACTERISTICS SPEEDS COMPUTED BY THE FMGC

Characteristic speeds computed by the FMGC are based on a predicted GW, CG (and selected configuration for landing) at a given time at landing for example.
GW and CG values are computed from entered ZFW and ZFWCG corrected for the predicted FOB and CG variation.
When the Approach phase is activated, the characteristic speeds are recomputed using the actual weight and CG.
The performance model used to compute the characteristic speeds, is accurate enough to provide speed errors of less than ± 2 kt from the certified speeds.



THE MOST FREQUENT QUESTIONS ON SPEED COMPUTATION

- **Why are the characteristic speeds computed by the FAC subject to inaccuracy greater than FMGC computation?**
  Answer:
  The precision of the AOA measurement is usually the cause of speed differences.
  An error of 0.3 ° in AOA measurement causes a weight inaccuracy close to 3 t.
- **Is the FMGC computation more accurate than the FAC computation?**
  Answer:
  Algorithms are the same but the initial data are different.
  The FAC computes current dynamic speeds.
  The FMGS computes characteristic speeds for given phases (and configuration for landing).
  Usually, the FMGC characteristic speeds for landing are more accurate due to the tolerance of FAC inputs, if the ZFW was correct initially.

  Note: To determine the GW at landing, the FMGC uses the ZFW entered by the crew and adds the fuel on board.
  A significant difference between PFD and MCDU characteristic speeds may also indicate an error in the ZFW as entered by the crew

- **Why are there two characteristic speed calculations?**
  Answer:
  The computation done by the FAC is independent of any manually entered data and provides permanent speed values displayed on the PFD.
  During approach, the comparison of characteristic speeds allows the crew to detect any speed discrepancy which may affect approach and final phases.
- **When a difference exists between computed speeds from FAC and FMGC, what are the best speeds to be relied on ?**
  Answer:
  Whenever differences are observed, Airbus recommends to rely on QRH values.
  Refer to QRH/FPE-SPD Speeds.

GROUND SPEED MINI FUNCTION

Intentionally left blank

FCB-FCB18-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Ground Speed Mini Function.....A

Intentionally left blank

GROUND SPEED MINI FUNCTION

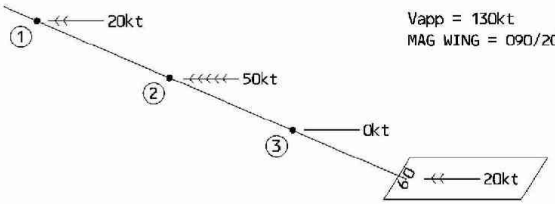
Applicable to: ALL

GENERAL

When an approach is flown in managed speed mode, the crew will notice that the target speed (magenta) displayed on the PFD, is variable during the approach.
This approach target speed, also called IAS target, is computed in the FMGS using the "ground speed mini function".
The purpose of the Ground speed mini function is to take advantage of the aircraft inertia, when the wind conditions vary during the approach. The aircraft flies a target speed during the approach and the energy of the aircraft is maintained above a minimum level ensuring standard aerodynamic margins over stall.
If the A/THR is active in SPEED mode, it will automatically follow the IAS target, ensuring efficient thrust management during the approach.

PRINCIPLE

The minimum energy level is based upon the ground speed the aircraft should have at touchdown, when landing at VAPP with the expected wind. It is called "GROUND SPD MINI".
During the approach, the FMGS continuously computes the IAS target to keep the ground speed at or above the "Ground Speed Mini", based upon the actual winds.
This IAS target is limited to VAPP
The IAS target is displayed on the PFD speed scale in magenta, when approach phase and managed speed are active. It is independent of the AP/FD and/or the A/THR engagements.
The following examples provide a comparison between the ground speed mini function versus the conventional selected speed hold function, in terms of speed target, and thrust management during an approach where winds are varying.



Conventional selected speed hold function	GS mini function
(1) Headwind 20 kt 140 120 N1 = 55% Speed Target 130 kt	**(1) Headwind 20 kt** 140 120 N1 = 55% IAS target 130 kt
(2) Headwind increases to 50 kt 160 140 120 * Current speed increases * Speed Trend is going up. * Thrust will be reduced to IDLE in order to match the speed target which remains unchanged.	**(2) Headwind increases to 50 kt** 160 140 120 * IAS target and current speed increases. * Speed trend is going up. * Thrust will be increased
(3) Headwind decreases to 0 kt 140 120 * Current Speed drops down * Speed Trend goes down. * Thrust is initially low and can be close to IDLE.	**(3) Headwind decreases to 0 kt** 140 120 * Current speed drops down from a higher speed. * Target speed drops down to VAPP * Speed trend goes down. * Thrust is initially high.
===> A/C energy is low. Thrust has to be significantly increased.	===> A/C energy is high. Thrust has to be smoothly reduced.

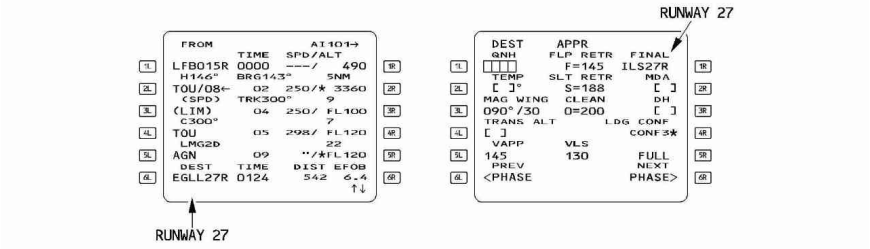
Ground speed mini function provides all the information necessary to manage the thrust smoothly and efficiently during the approach, in the event of gusts or horizontal windshears.

BASIC COMPUTATION

Wind is a key factor in the ground speed mini function.

TOWER WIND

It is the MAG WIND entered in the PERF approach page. It is the average wind as provided by the ATIS or the tower. Gusts are not inserted; they are taken into account during ground speed mini computation.



TOWER HEADWIND COMPONENT

Component of the MAG WIND relative to the FMS runway axis.
The FMS Runway axis is the landing runway axis entered in the F-PLN and indicated on the PERF APPR page.

CURRENT WIND COMPONENT

Component of the actual wind measured by ADIRS, relative to the aircraft axis.
The three following formulae explain how the approach speed target (IAS target) is computed using the ground speed mini function. Note that this computation is different for the A320 and the A319, A321 or A320 with the modification which reduces VAPP (mod 25225).

VAPP Computation

	VAPP COMPUTATION
A320	VAPP = VLS + 5 kt + 1/3 OF THE TOWER HEADWIND COMPONENT
A320 with Mod 25225 A319/A321	VAPP = VLS + MAX (5, 1/3 OF THE TOWER HEADWIND COMPONENT)

Wind correction limit: mini 0 kt, maxi 15 kt
VAPP may be changed manually by the crew if desired.
The 5 kt increment to VLS is an Airworthiness requirement when autoland is used. (CAT 2 - CAT 3)
Tower headwind component is counted positively.
In case of a tower tailwind, the wind correction is zero and VAPP = VLS + 5.

Ground Speed Mini Computation

The ground speed mini value is not displayed to the crew, but it is of interest to understand its principle.
GS mini = VAPP - TWR HEADWIND COMPONENT

- The TWR HEADWIND COMPONENT is counted positively
- The TWR HEADWIND COMPONENT is counted positively
- If the TWR HEADWIND COMPONENT is below 10 kt or if there is a TWR TAILWIND COMPONENT, GS mini = VAPP -10

Approach Speed Target Computation (IAS Target)

Approach speed target, also called IAS target is computed as the higher of:
- VAPP
- GS mini plus current wind component

IAS target = MAX (VAPP, GS mini + CURRENT WIND COMPONENT)
CURRENT HEADWIND COMPONENT is counted positively. CURRENT TAILWIND COMPONENT is counted negatively.
No max value limitation exists.

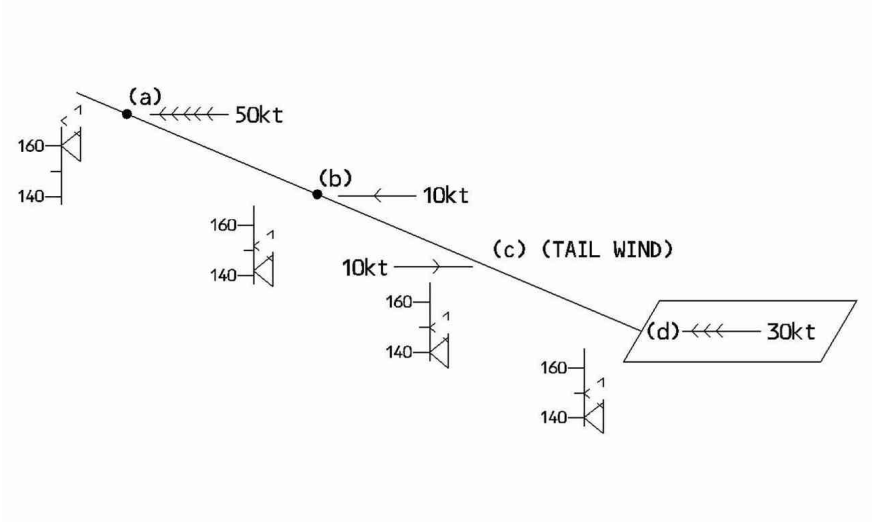
EXAMPLES

NORMAL APPROACH

- Approach on Runway 09 - FMS Runway 09
- TWR wind on PERF APPR page: 090/30
- VLS = 130 kt

COMPUTATION	A320 (basic configuration)	A320 (with Mod 25225) A319 - A321
VAPP	$\text{VAPP} = 130 + 5 \ + \frac{1}{3}\text{of} \ \ 30$ $= 145\text{kt}$	$\text{VAPP} = 130 + \text{MAX}(5, \frac{1}{3}\text{of}\,30)$ $= 140 \text{ kt}$
GS Mini	GS Mini = 145 - 30 = 115 kt	GS Mini = 140 - 30 = 110 kt

Current wind in Approach	IAS target (◁) A320 (basic configuration)	IAS target (◁) A320 (with Mod 25225) A319, A321
(a) 090/50	MAX (VAPP, 115 + 50) = 165 kt	MAX (VAPP, 110 + 50) = 160 kt
(b) 090/10	MAX (VAPP, 115 + 10) = 145 kt	MAX (VAPP, 110 + 10) = 140 kt
(c) 270/10	MAX (VAPP, 115 - 10) = 145 kt	MAX (VAPP, 110 - 10) = 140 kt
(d) 090/30	MAX (VAPP, 115 + 30) = 145 kt	MAX (VAPP, 110 + 30) = 140 kt



CIRCLING APPROACH

The crew will insert (primary F-PLN) the instrument approach to be flown to MDA. The secondary flight plan should contain final approach for the landing runway with the associated wind information.
During the circling maneuver, the crew must activate the secondary in order to provide valid ground speed mini information.

Example:

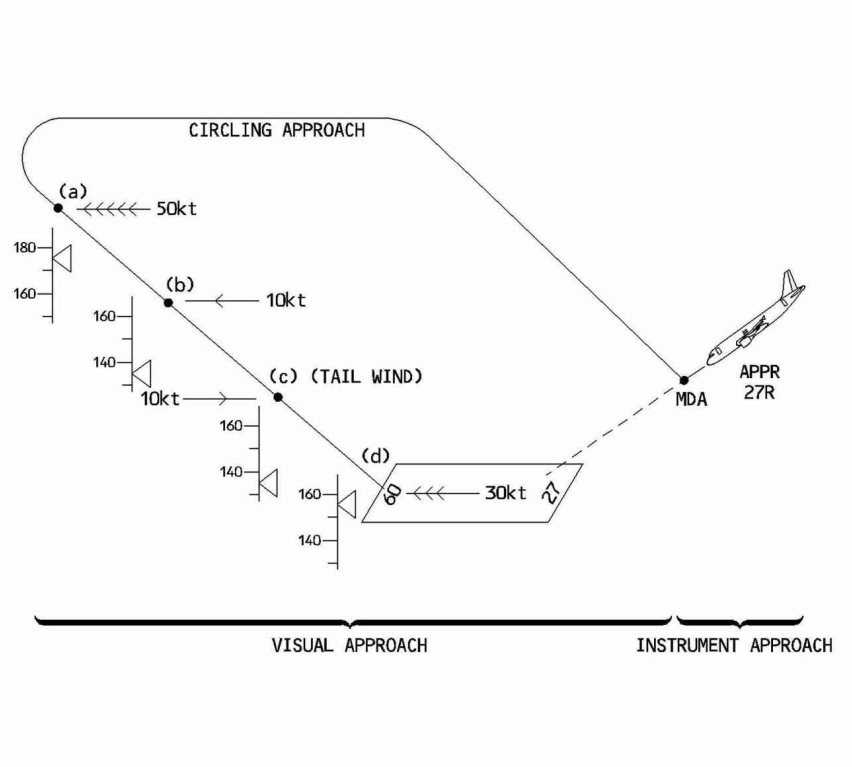
Instrument Approach on RWY 27
Circling Approach to RWY 09

Winds
a. 090/50 kt
b. 090/10 kt
c. 270/10 kt
d. 090/30 kt (TWR wind on PERF APPR)

VLS = 130 kt

The 3 formulae give the following results:

1. VAPP = 130 + 5 + Zero* = 135 kt for A320 basic configuration
   130 + MAX (5 kt, Zero*) = 135 kt for A320 with Mod 25225, A319, A321
   * wind is considered as tail wind because RWY 27 is selected in the F-PLN.
2. GS Mini = 135 - 10 = 125 kt (10 kt default wind value)
3. IAS target = MAX (135, 125 + current headwind component).



The IAS target is function of the runway which is selected in the active flight plan.
Let us consider that the aircraft is actually on Final Approach onto Runway 09, the approach target speed in final will vary as follows in case Runway 27 or Runway 09 are inserted in the FMS F-PLN:

Runway 27 selected in the F-PLN
VAPP = 135 kt
GS MINI = 125 kt

A320 (basic configuration)
Runway 09 selected in the F-PLN
VAPP = 145 kt
GS MINI = 115 kt

A320 (Mod 25225) A319, A321
Runway 09 selected in the F-PLN
VAPP = 140 kt
GS MINI = 110 kt

SELECTED RUNWAY IN F-PLN	VAPP VALUE (PERF APPR PAGE)	GS MINI	ENCOUNTERED WINDS	IAS TARGET IN FINAL FOR RUNWAY 09
(1) RUNWAY 09 A320	145 kt	115 kt	(a) 090/50 (b) 090/10 (c) 270/10 (d) 090/30	165 kt 145 kt 145 kt 145 kt
(1) RUNWAY 27 A320 (Mod 25225) A319, A321	140 kt	110 kt	(a) 090/50 (b) 090/10 (c) 270/10 (d) 090/30	160 kt 140 kt 140 kt 140 kt
(2) RUNWAY 27	135 kt	125 kt	(a) 090/50 (b) 090/10 (c) 270/10 (d) 090/30	175 kt 135 kt 135 kt 155 kt

CONCLUSION

If the landing runway inserted in the FMGS F-PLN is different from the actual landing runway, MANAGED APPROACH SPD shall not be used since the resulting targets may be significantly too high. (This rule applies wherever the FMS landing runway axis is different by 30 ° the actual landing runway axis).
In this case, select the approach speed directly on the FCU.

EMERGENCY LIGHTING SYSTEM

REASON FOR ISSUE

Some cases of exit signs not illuminating during takeoff, landing and on ground have been reported.
In normal operation with the "EMER EXIT LT sw"4WL (25VU) in "ARM" position and the "NO SMOKING sw"190RH (25VU) in auto position the exit signs extinguish only when the "NO SMOKING" signs extinguish at landing gear retraction and illuminate again at landing gear extention.
Investigation revealed that the emergency power supply unit could remain frozen after power transfer.

PROCEDURE

During taxi and before landing check exit signs for proper illumination.

If one or more exit signs are not illuminated, perform a reset of the emergency power supply by:

1. From attendant panel:
   - Press the "EMERGENCY pb"120RH once on flight attendant panel
   - Wait approximately 4 s
   - Press the "EMERGENCY pb"120RH again to recover normal configuration.

   or
2. From the cockpit:
   - Select the "EMER EXIT LT sw"on panel 25VU to "ON" position
   - Select the "EMER EXIT LT sw"to "ARM" position.

If normal operation is not recovered, maintenance action is due before the next flight unless the dispatch is authorized by the MEL.

DELIBERATE INHIBITION OF AMBIENT LAVATORY SMOKE DETECTORS

(A/C with MOD 22561)

EXPLANATION

When the smoke detector grill is removed and foreing objects like tissue paper or plastic bags are packed around the detector (see graphic below), the result will have a serious impact on the detection system. The detector may not be able to "sample" the air.

PROCEDURE

The cabin crew is recommended to inspect the lavatory smoke detectors for tampering before every flight. If foreign bodies or sign of tampering are found, line maintenance should be informed.

VACUUM TOILET RINSE VALVE LEAKAGE

(A/C with MOD 26145)

EXPLANATION

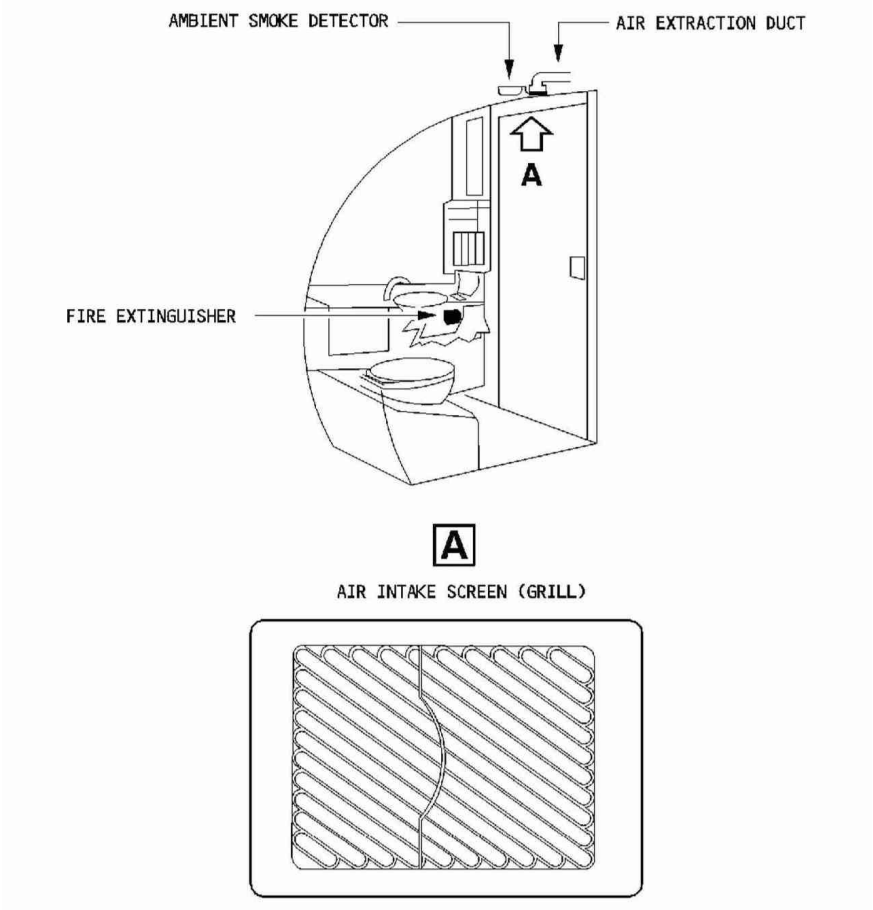
An increase in vacuum toilet rinse value leakage has been experienced. Leakage at the vacuum toilet rinse valve in the forward lavatory may lead to water flooding in the cockpit with possible water spillage in the avionic bay.

ACTION

Airbus Industrie has initiated a modification consisting of the introduction of an improved rinse valve.

PROCEDURE

Pending the introduction of the improved rinse valve, it is recommended that the cabin crew perform a toilet flush in each lavatory before the first flight of the day. This should minimize the effect of possible overnight deposit inside the valve by draining the content.
The cabin crew should advise the maintenance if abnormal water accumulation is found.



This grill is a cover for the ambient smoke detector and the air extraction duct. The view shown is how the grill would appear when looked at from below.
This grill can be removed. Foreign objects (tissues, plastic bags) have been found packed around the ambient smoke detector.

FCB-FCB22-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

EGPWS Database..... A

Intentionally left blank

EGPWS DATABASE

Applicable to: ALL

PURPOSE

Airbus has received some reports of EGPWS warnings that were unduly triggered due to airport data missing from the database.
It is the Airlines responsibility to identify the airport(s) where the terrain data is missing from the database. During operation around such airports, the enhanced function must be switched off (TERR pb OFF on overhead panel) when the aircraft position is less than 15 nm from the runway.
The purpose of this bulletin is to provide the operators and the flight crews with additional information regarding the EGPWS database and the EGPWS system reaction when the airport/terrain data is not included in the database.
The FCOM-LIM-34 (*Refer to LIM-34 Enhanced Ground Proximity Warning System (EGPWS)*) and AFM-LIM-34 (*Refer to AFM/ 00006966 **Not found***) provide limitations of the system.

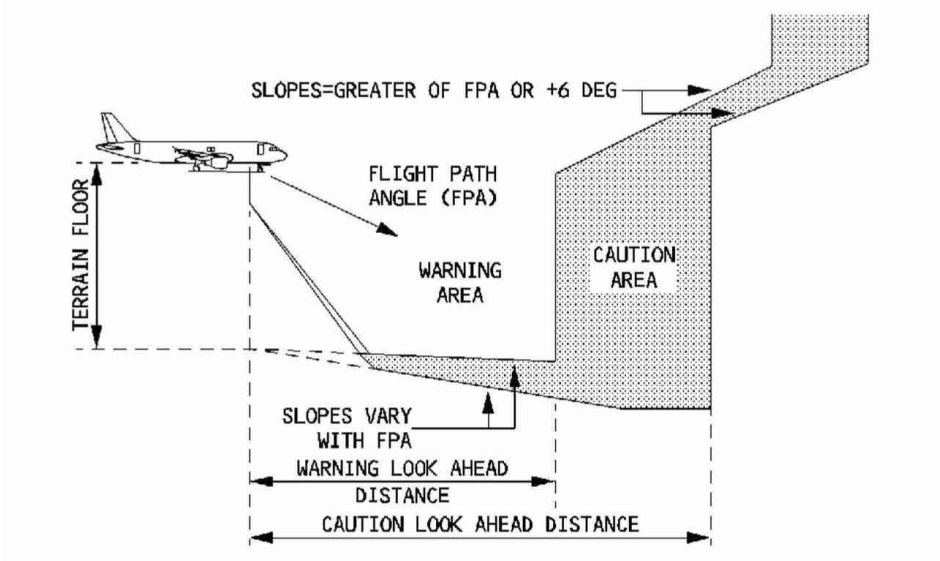
1. THE ENHANCED GPWS FUNCTIONS

The purpose of the Enhanced Ground Proximity Warning System (EGPWS) is to alert the crew of potential hazardous conditions with regards to Controlled Flight into Terrain (CFIT).

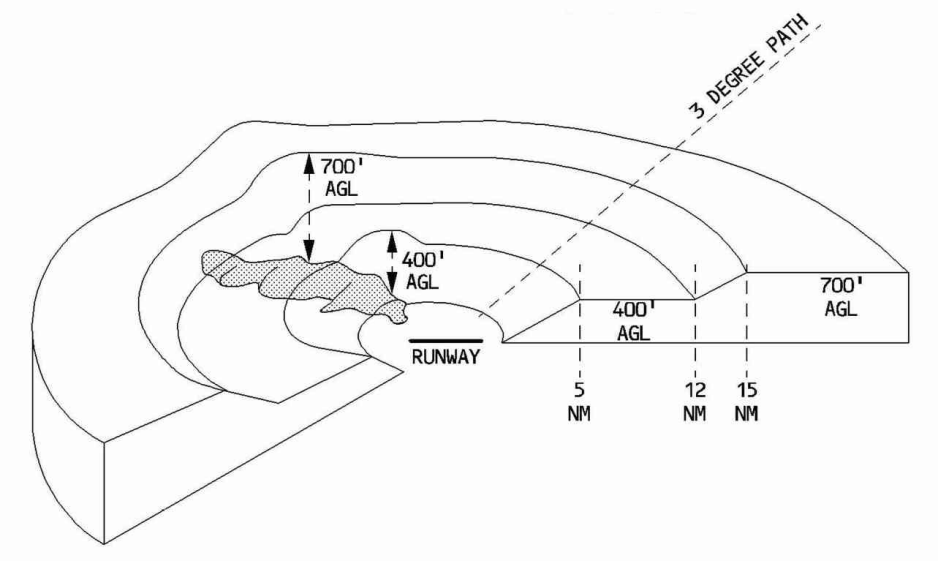
Two enhanced functions have been added to the basic modes of the GPWS. These functions are the following:

- Terrain Awareness and Display (TAD)
- Terrain Clearance Floor (TCF)

• The Terrain Awareness and Display (TAD) function compares the aircraft FMS position with the local terrain in the database. It also computes two envelope boundaries ahead of the aircraft. When terrain data conflicts with one of these envelopes, specific aural and visual alerts are triggered.
This function also provides terrain data display on the Navigation Display (ND)



• The Terrain Clearance Floor (TCF) function computes a terrain clearance envelope around the airport runway. It is based on current aircraft location, nearest runway center point position included in the database and radio height. When the aircraft enters this envelope, an alert "TOO LOW TERRAIN" is produced even if the aircraft is in landing configuration. This alert protects against an attempt to land where there is no airfield. This can be the case for example when descending by mistake on a wrong vertical path during a non-precision approach. This function operates during any flight phase.



2. THE EGPWS DATABASE

The terrain database divides the Earth surface into grid cells. These cells are recorded upon the WGS-84 geographic coordinate system for longitude and latitude data. Each cell records the highest terrain altitude in the respective terrain area.

The resolution of the grid varies upon the geographic location, ranging from:
- 0.25 nm x 0.25 nm
- 0.5 nm x 0.5 nm
- 1 nm x 1 nm
- 2 nm x 2 nm
- 5 nm x 5 nm.

The highest resolution (0.25 nm x 0.25 nm) is used around the airports. This is to avoid producing alerts during normal procedures (the terrain database has to reflect as closely as possible the actual terrain). The lowest resolution (5 nm x 5 nm) is used outside airports where such a coarse terrain database cannot interfere with normal en-route trajectories. The database also contains the position of the airport runway center point. This concerns all hard surface runways (whatever the surface type is) longer than or equal to 3 500 ft.
Additionally, the database gives the possibility of incorporating data regarding man-made obstacles in the vicinity of the major airports.

3. EGPWS REACTION WHEN AIRPORT DATA IS MISSING FROM THE DATABASE.

When an airport/terrain data is not yet covered by the database, the TCF envelope cannot be defined. The system uses the lowest map resolution (5 nm x 5 nm) as no airport is detected. Therefore, early and unexpected TAD cautions and warnings are triggered. The red EGPWS legend of the GPWS/G/S pb comes on, the aural warnings "TERRAIN AHEAD" and "TERRAIN AHEAD, PULL-UP" sound and the terrain image pops up on the Navigation Display. When within 15 nm, it is recommended to switch off the enhanced functions (EGPWS TERR pb switched to OFF on overhead panel) for operations from/to runways not incorporated in the database (*Refer to LIM-34 Enhanced Ground Proximity Warning System (EGPWS)*).

4. THE EGPWS DATABASE UPDATE

The database update is under the responsibility of the vendor.

The vendor may use one or more sources of data for a particular airport:

1. Data from in-country government and/or regulatory agencies
2. Data from airlines that have surveyed an airport while establishing layout, approach/departure procedures, etc.
3. Data from commercial vendors who also produce data sets for FMS and other navigational systems
4. Data from commercial and military surveying agencies that make such information publicly available
5. Airport layout and physical properties from high-resolution maps and/or digitized data sources
6. Airport layout and physical properties from imagery.

Some difficulties may be encountered in some areas to compile and validate airport data.
For an official indication of the latest EGPWS database, as well as a list of covered airports, please review the manufacturer document, EGPWS Terrain Database Airport Coverage list.
More information can be found on the Honeywell website:
WWW51.honeywell.com/aero/

5. CONCLUSION

The enhanced functions of the EGPWS are not reliable when operating around airports which are not included in the database. In this case, these functions must be switched off (TERR pb off on the overhead panel).
It is the airlines responsibility to identify with the database manufacturer the airports where terrain data is missing.
Airbus strongly recommends to the airline to report to the database manufacturer and to their local airworthiness authorities any EGPWS warning occurrence due to airport data missing from the database. It is also recommended that airlines request that their national authorities publish the

necessary data in order that the database manufacturer can extend the database coverage to all operated airports.

FCB-FCB23-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Use of Managed Guidance in Approach and NAV Database Validation..... A

Intentionally left blank

USE OF MANAGED GUIDANCE IN APPROACH AND NAV DATABASE VALIDATION

Applicable to: ALL

1. BACKGROUND

The purpose of this FCOM Bulletin is to highlight SOP recommendations on the use of managed guidance in approach.
The current body of published Instrument Approach Procedures (IAP) includes "old style" procedures, based on conventional radio NAVAIDs which cannot always be coded in the navigation database, in a suitable manner for satisfactory FMGS guidance in approach.

Note: *RNAV procedures are usually designed and coded for optimum FMGS guidance in FINAL APP mode.*

For conventional NPA using FMS managed lateral and vertical guidance, if the navigation database has been obtained from approved suppliers compliant with the requirements of ED76/DO200A, the validation of the approach coded in the database can be deferred to the flight crew, checking the FM F-PLN (on MCDU and ND) against the published approach chart.

Note: *Conventional radio NAVAIDs must be available and monitored during the approach, and must be considered as the primary means of navigation.*

For RNAV approaches using FMS managed lateral guidance only, based on the provisions of AMC 20 XZ (draft), if the navigation database has been obtained from approved suppliers compliant with the requirements of ED76/DO0200A, the validation of the approach lateral flight path coded in the navigation database can be deferred to the flight crew, checking the FM F-PLN (on MCDU and ND) against the published approach chart.

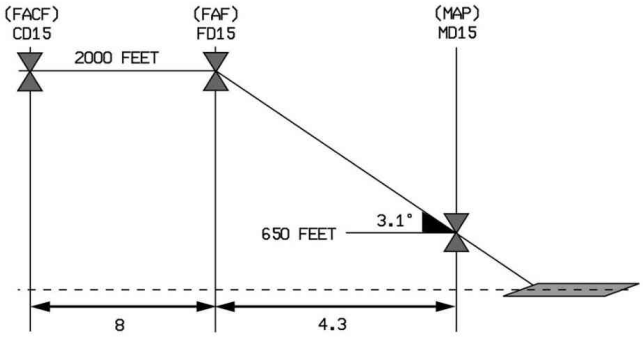
Note: *When flying an RNAV approach using NAV mode associated with selected vertical guidance (FPA, V/S), the distance to the runway or the MAP versus altitude is the primary means of vertical navitation, the vertical deviation on the PFD may be unreliable.*

For RNAV approaches using FMS managed lateral and vertical guidance, the vertical flight path coded in the navigation database must be validated by the operator.
Validation of the navigation database should ensure that the IAP is of an eligible type, and is correctly coded so that the aircraft in FINAL APP mode will fly a constant flight path angle from the FAF to the runway with the required obstacle margins.
Different methods or processes can be used to validate the IAP that is coded in the navigation database.
One method is to fly each approach in a simulator (or equivalent device), or with the aircraft when weather conditions are good. An IAP that is regularly and correctly flown in FINAL APP mode can be considered as validated.
Another method is to use a dedicated software to read the navigation database diskette. The listing or display of the coded IAP is then assessed by comparing it with the approach chart. The

airline should keep an up-to-date record of the IAPs that are approved for the use of FINAL APP mode.

2. IAP AND CODING REQUIREMENTS

A number of FMGC coding guidance requirements have been identified, and must be considered, when performing navigation database validation for the use of managed guidance in approach. As an example, the following drawings show the coding of an VOR DME IAP (with the MAP before the runway), and the associated MCDU display. Refer to drawings below.



FACF = Final Approach Course Fix
FAF = Final Approach Fix
MAP = Missed Approach Point

= Waypoints with associated altitude constraints

	UTC	SPD / ALT
-----	----	---- ----
C144°		
CD15L	----	---- * 2000
C144°	TRK144°	8
FD15L	----	---- * 2000
C144°		4 -3.1°
MD15L	----	---- 650

The final approach consists of a sequence of at least two waypoints. However, it more often consists of 3, or 4, waypoints.
In the above example, the 3 waypoints are the FACF, the FAF, and the MAP. Sometimes, the MAP is located at, or after, the runway threshold. We will see that it is important for the crew to

identify the MAP position. Sometimes, a Step Down Fix (SDF) is added on the approach final descent, between the FAF and the MAP.
The SDF is not necessarily identical to the waypoints published on the approach chart. The identification of the waypoints shown on the MCDU often differs from the identification shown on the approach chart.

THE LATERAL F-PLN CODING REQUIREMENTS

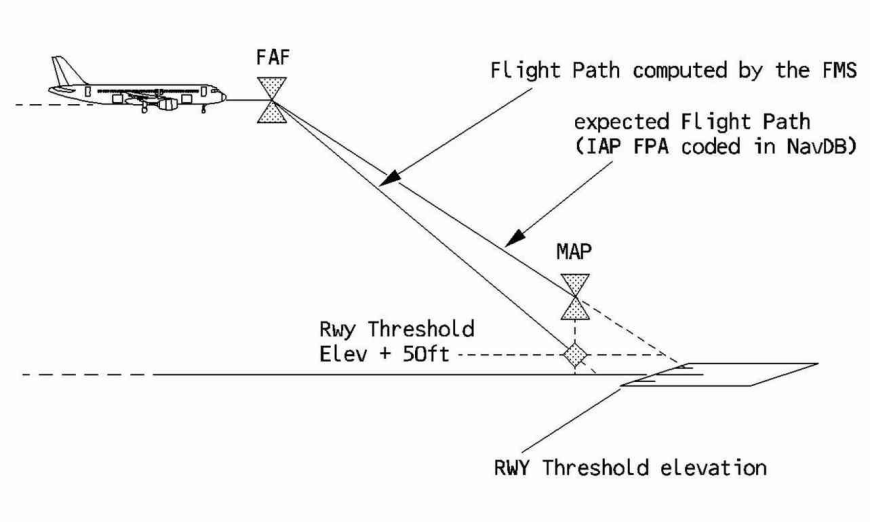
The FACF and the FAF must be aligned with the approach course.
If the FACF and the FAF are collocated, the course change at the FAF should be small. A sharp turn would prevent the aircraft from overflying the FAF, and the final descent would start before the FAF, without the aircraft being established on the final approach course.
For aircraft equipped with Honeywell FMS, approach procedures, including a PI-CF Leg (PROC T displayed between 2 approach waypoints on the MCDU F-PLN page), are not permitted with AP or FD managed guidance.
These approaches must be flown in selected guidance, using published approach chart and NAVAID raw data.

THE VERTICAL F-PLN CODING REQUIREMENTS

An altitude constraint must be coded at each approach waypoint.
Any waypoint of the approach should not be common to a STAR or a VIA waypoint with different altitude constraints. Combining altitude constraint may lead to erroneous vertical flight path guidance.
An AT or ABOVE constraint can be used for an SDF.
When the **MAP is located at, or before, the runway threshold, an FPA** (≠ 0 °) **must be coded at the MAP. or at the runway threshold (RW). This FPA will appear on the MCDU, between the MAP and the FAF, or any previous SDF in the final approach.**
When the **MAP is located after the runway threshold, an FPA =** 0 ° **must be coded at the MAP.**
For these "old style IAP", with the MAP after the runway threshold, and depending on the position of the approach axis relative to the runway, FMGC guidance may start the final approach descent slightly before the FAF. In most cases, the crossing altitude difference at the FAF is not significant (less than 50 ft). But, sometimes, this difference may be higher. Therefore, as it is not acceptable for the use of FINAL APP mode, we recommend validating the IAP with a MAP after the runway threshold, either in a simulator (or equivalent device), or with the aircraft in good weather conditions.
An FPA (≠ 0 °) must be coded for each SDF that is on the final approach descent. The MAP of an RNAV IAP must be located at the runway threshold.
Additional vertical requirements for RNAV approaches (for Honeywell FMS only)
The MAP of RNAV approaches must be located at the runway threshold.

Whenever the FMGC identifies an IAP labelled RNAV, it constructs the vertical flight profile assuming that there is an altitude constraint at the MAP equals to the runway threshold plus 50 ft. If the MAP is located significantly before the runway threshold, the FMGC computes an incorrect vertical flight path, and will display a wrong vertical deviation indication (VDEV) on the PFD.
Consequently, the MAP crossing altitude on the F-PLN page will be incorrect compared to the published value.
As a result, an RNAV IAP with a MAP located before the runway threshold must not be validated to be flown with the full FMS managed mode FINAL APP.

Note: *The approaches labelled "GPS"are not affected and can be flown in FINAL APP mode.*



3. FLIGHT CREW PROCEDURES

The SOP (Refer to PRO-NOR-SOP-19) for Non Precision and RNAV approaches are applicable.
The following recommendations are provided to highlight specific vertical navigation aspects, when FINAL APP mode is used.
As applicable, the crew should first check that the Airline has approved the approach for FINAL APP mode use.

3.1 APPROACH F-PLN VERIFICATION

Before starting the approach, the crew must check the FMS F-PLN (on the MCDU, and on the ND in PLAN mode with the CSTR displayed), starting from the beginning of the STAR down to

the runway and the missed approach procedure, and verify the profile against the published IAP chart.

For the final approach procedure, the crew should check the:

- Approach course
- Waypoints and associated altitude constraints
- IAP must not include a Procedure Turn (PROC T indicated on the MCDU)
- Distance from the FAF to RW, or FAF to MAP
- Approach angle (shown on the MCDU line above the related waypoints):
  - **If MAP. after the runway threshold: FPA =** 0 ° **at MAP**
  - **If MAP before or at runway threshold: FPA ≠** 0 ° **at MAP**
  - **For each Step Down Fix, an FPA ≠** 0 ° **must be defined**
- **IAP does not include a PI-CF leg (PROC displayed on the MCDU)**
- **MAP of an RNAV IAP must be located at the runway threshold.**

  Note: *The MAP of a GPS IAP can be located before the runway threshold.*

- Altitude at the MAP, or at the runway threshold:
  If the crossing altitude at MAP is not shown on the approach chart, crosscheck consistency with the distance to the runway and the approach angle.

3.2 LIMITATIONS TO APPROACH F-PLN MODIFICATIONS

When performing an IAP, using NAV and FINAL APP modes, the active F-PLN, extracted from the navigation database, can be modified, provided the following limitations are observed:

1. F-PLN modifications:
   - No lateral modification of the F-PLN from FACF (inclusive) to RW or to MAP.
     A modification is permitted before FACF, provided the resulting change in the flight path course is not so large that it prevents the aircraft from being laterally-stabilized on the final approach course before reaching the FAF.
   - No altitude constraint modification from FACF to MAP. Even in case of a very low OAT, no altitude correction can be entered in this way. This may require that a minimum OAT be defined, so that the vertical flight path will clear obstacles with the required margin. This minimum OAT should be given to the crew, when appropriate. In the future, for RNAV approaches, the minimum OAT will be published on the approach chart itself.

- When the FAF is the TO waypoint, the FROM waypoint must not be cleared in an attempt to perform a DIR TO/INTERCEPT.
- To benefit from managed speed, and have a correct location of the DECEL point, it is recommended to enter VAPP as a SPD CSTR at FAF.

2. DIR TO...
   - DIR TO FACF is permitted, provided the resulting change in flight path course at FACF is not so large that it prevents the aircraft from being laterally-stabilized on the final approach course before reaching the FAF.
   - DIR TO FAF is permitted, provided the resulting change in flight path course at FAF is small.
   - For aircraft with FMS 2: DIR TO/INTERCEPT TO FAF is permitted, provided the RADIAL IN corresponding to the final approach course (approach course + 180 °) is selected, and that the interception angle is not so large that it prevents the aircraft from being laterally-stabilized on the final approach course at the FAF.
3. Lateral F-PLN interception in HDG/TRK:
   - F-PLN must be intercepted before the FACF, and the interception angle should not be so large that it prevents the aircraft from being laterally-stabilized on the final approach course before reaching the FAF, or
   - Before FAF, at the latest, provided the interception angle is small.

CAUTION	- Before arming NAV, check that the correct "TO"waypoint is displayed on the ND. - The intercept path in HDG/TRK must not cause premature sequencing of the FAF. The FAF should be sequenced in NAV mode, when established on the final approach course.

4. Vertical F-PLN interception:
   - The crew should manage the descent, so that the vertical F-PLN is intercepted before the FAF, at the latest.

3.3 APPROACH MONITORING

Except for RNAV IAP, approach NAVAIDs should be tuned and the associated raw data should be displayed and actively-monitored. This active monitoring should include vertical navigation, using altimeter readings versus DME distances or the equivalent.
For RNAV IAP, vertical navigation can be monitored by using the distance to the RW, or to the MAP displayed on the ND, and the altimeter reading.
After passing the FAF, when stabilized on the final descent, the crew should check that the X-TRK and VDEV are correct, and that the FPV is consistent with the approach angle.

When APPR is selected on the FCU, the crew must verify the:
- Correct FMA display (APP NAV green, FINAL blue)
- Correct TO waypoint on the ND

- Blue descent arrow at FAF and the correct F-PLN
- Correct Vertical Flight Path deviation indication

When passing the FAF, the crew must verify:
- Correct altitude indication
- Correct FMA display (FINAL APP green)
- Correct TO waypoint on the ND
- Correct blue track on the ND, armed for Missed Approach
- That the aircraft starts the descent and follows the correct lateral and vertical flight path.

If HIGH ACCUR is lost during the approach, but active radio NAVAID monitoring confirms correct navigation, the approach can be continued in FINAL APP mode. Otherwise, the crew should revert to TRK/FPA mode to fly the aircraft with NAVAIDs raw data.

The IAP must be discontinued, when one of the following warnings occurs:
- GPS PRIMARY LOST, if GPS accuracy is required
- NAV ACCUR DOWNGRAD, during an RNAV approach
- FM/GPS POS DISAGREE, if GPS is installed and is not deselected, and if no NAVAID raw data is available to revert to selected modes
- FM 1/FM 2 POS DIFF, unless NAVAID raw data is available to revert to selected modes.

3.4 CREW REPORTING

The crew must report any lateral or vertical NAV guidance anomaly to their Flight Operations. The report must be fully-documented to enable further investigation and corrective actions:

It should, therefore, include the following information:
- Approach designation and airport
- Aircraft type, MSN, GW, wind/temperature
- Navigation database cycle
- Pilot selections, FMA, ND, MCDU displays
- Description of anomaly, flight path
- DFDR/QAR reading.

AIRCRAFT HANDLING IN FINAL APPROACH

Intentionally left blank

FCB-FCB24-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Aircraft Handling in Final Approach..... A

Intentionally left blank

AIRCRAFT HANDLING IN FINAL APPROACH

Applicable to: ALL

REASON FOR ISSUE

During the approach, with the A/THR active, Airbus recommended to set the thrust levers above the CL detent (but below the MCT detent), in exceptional circumstances, if the speed significantly dropped below VAPP. However this procedure is not trained and proved to have more drawbacks than advantages. Therefore, Airbus no longer recommends to use this procedure. The procedure is deleted from the operational documentation.
If the A/THR performance is not satisfactory, the flight crew should take over, and control the thrust manually.

GENERAL

The purpose of this FCOM Bulletin is to highlight certain aspects of aircraft handling during final approach, and to illustrate that the feedback received from in-service experience merits further attention.
Although approach in turbulence is part of this discussion, windshear in approach is not addressed here. For more details on the subjects of "Windshear in Approach" and "Operations in Windshear or Downburst Conditions", *Refer to PRO-SUP-91-20*.

APPROACH STABILIZATION CRITERIA

The prerequisite for a successful final approach and landing is to stabilize the aircraft on the final approach trajectory in pitch, thrust, airspeed, and bank angle.

This signifies that the:
- Aircraft is established on the:
  - Final approach trajectory, and only minor heading corrections are necessary (except for indirect or curve approaches) to correct the effect of external conditions, acting on the roll axis
  - Final approach vertical flight path, and only minor pitch corrections are necessary to correct the effect of external conditions;
- The target speed is maintained on the desired descent path, with the appropriate thrust (not stabilized at idle).

Airbus policy requires that stabilized conditions be reached at 1 000 ft Height Above Threshold in IMC, and 500 ft feet in VMC, and that they be kept down to the flare height.
In turbulent conditions, there may be heading, pitch, and thrust corrections of such a magnitude that it could be difficult to determine when to consider the approach stabilization criteria as being lost. Thrust corrections, in particular with the A/THR ON, could lead engines to temporarily reduce thrust to idle, which may not be desirable close to the ground, if the aircraft level of energy is low.
The PNF callout for excessive deviation is certainly an indication for the PF to decide/determine if the approach becomes destabilized. However, the answer to this question is generally a matter of

pilot judgement. The pilot must assess whether or not it is possible to return to nominal conditions early enough: That is, at the latest before flare initiation. If the pilot judges that it will not be possible to start the flare at the correct height with the correct attitude, sink rate, and thrust, or if the pilot starts to feel "out of the loop", then it is time to perform a go-around.

PNF CALLOUT

In approach, the PNF is expected to monitor the PFD and to make a callout, when some parameters are exceeded.

The Airbus FCOM Standard Operating Procedures (*Refer to PRO-SUP-91-20* and *Refer to PRO-NOR-SOP-18* and *Refer to PRO-NOR-SOP-19*) state that a callout should be made, if:
- Speed becomes lower than the speed target -5 kt, or greater than the speed target +10 kt
- Pitch attitude becomes lower than 2.5 ° nose down, or greater than 10 ° nose up
- Bank angle becomes greater than 7 °
- Descent rate becomes greater than 1 000 ft/min
- Excessive LOC or GLIDE deviation occurs (*Refer to PRO-NOR-SOP-18* only).

The suitable PF response would be to immediately take appropriate actions to control the exceeded parameter and evaluate whether stabilized conditions will be recovered early enough. Otherwise, a go-around must be initiated. The PF should acknowledge the PNF callout so that crew coordination remains effective.

AIRCRAFT HANDLING ON THE LONGITUDINAL AXIS

The pilot's objective, with respect to the longitudinal axis, is to control the airspeed and the vertical flight path. For thrust and speed control, it is recommended to use FMGS managed speed, in order to benefit from the minimum GS function.
The A/THR is, in particular, best suited to tracking a moving target speed, when flying in managed speed mode. Statistically, the A/THR provides the best protection against airspeed excursions and its use is, therefore, recommended even in turbulent conditions, unless thrust variations become excessive.
A/THR response to airspeed variations is the result of a design compromise between performance and comfort, and it is optimized when the AP is engaged. Therefore, in turbulent conditions and when flying manually, the pilot may sometimes find it to be too slow or lagging.
If conditions are such that a large speed decrease with engines at idle is anticipated, then the PF may take over thrust manually to recover the speed target and continue the approach in manual thrust.
It is not recommended to use the speedbrakes in the final approach. In final approach, the drag with the Landing Gear down is normally sufficient to cope with all kinds of situations, including a tailwind landing.
The pilot's objective, with respect to vertical navigation, is to maintain a constant flight path angle down to the runway threshold, using the vertical deviation indication of an ILS, the FMGS

VDEV indication, the indication of an external lighting system, or visual cues. However, when approaching flare height, the pilot's primary objective will progressively shift from vertical flight path control to safe pitch attitude and vertical speed, to start the flare in good conditions. The PF will primarily control the attitude and the vertical speed to perform a safe flare.

If the vertical speed is too high, prior to starting the flare, the vertical deceleration that can be achieved during flare may be insufficient to avoid a hard landing. The aircraft may touch down with an excessive residual vertical speed and pitch rate, which may lead to bouncing and exposure to tailstrike.

The pilot should also consider that the flare height might vary slightly from one aircraft type to another, depending on aircraft inertia. In the event of turbulence and wind gradient, pitch monitoring is of primary importance when close to the ground. The pilot should react promptly to any uncommanded pitch down tendency, to avoid ducking under, with a risk of premature touchdown.

If vertical speed and pitch attitude become the primary objectives, the touchdown point might occur slightly further ahead on the runway, thereby reducing the available stopping distance. In the large majority of landings, and based on the pilot's judgement, this effect should be acceptable. However, in case of doubt, it is always best to perform a go-around.

AIRCRAFT HANDLING ON THE LATERAL AXIS

Generally speaking, lateral handling of fly-by-wire aircraft is conventional. But, in very gusty conditions, it is necessary to recall the principle of the flight control law in roll. With the sidestick, the pilot can order a roll rate up to a maximum of 15 °/s. However, the aerodynamic capacity of the roll surfaces, when fully deflected, is much higher: That is, up to about 40 °/s. This means that, if the aircraft is flying through turbulence that produces a roll rate of 25 °/s to the right, the aircraft still has the capacity to roll to the left at a rate of 15 °/s, with full sidestick command. This is more than what is necessary in the worst conditions.

The sidestick's ergonomical design is such that the stop at full deflection is easily reached. This may give the pilot the impression that the aircraft is limited in roll authority, because there is a time delay before the pilot feels the result of his/her action. On conventional aircraft, due to the control wheel inertia, the pilot needs considerably more time to reach the flight control stop.

The flight control system of Airbus fly-by-wire aircraft partially counteracts roll movements induced by the effect of gust, even with the sidestick in the neutral position. The PF must ensure that the overall corrective orders maintain the desired aircraft lateral axis. He/she will minimize lateral inputs and will resist applying sidestick order from one stop to the other.

Every sidestick input is a roll rate demand, superimposed on the roll corrections already initiated by the fly-by-wire system. The pilot should only apply "longer-term" corrections as needed.

Before flare height, heading corrections should only be made with roll. As small bank angles are possible and acceptable close to the ground, only small heading changes can be envisaged. Otherwise, a go-around should be initiated.

Use of rudder, combined with roll inputs, should be avoided, since this may significantly increase the pilot's lateral handling tasks. Rudder use should be limited to the "de-crab" maneuver in case of crosswind, while maintaining the wings level, with the sidestick in the roll axis. (Refer to the FCOM's SOP, for Crosswind Landing Techniques).

SUMMARY

In summary, the following are the main points addressed by this Bulletin:

- Strictly observe the approach stabilization criteria to decide whether to land, or to perform a go-around
- Promptly react to any pitch down at low height, to avoid ducking under
- Reach the flare height with the correct pitch attitude and sink rate
- In turbulent conditions, it is recommended to use the A/THR, unless the PF is not satisfied by the A/THR response
- Refrain from excessive sidestick roll activity. Order "longer-term" roll corrections
- Restrict rudder use to "de-crabbing" in crosswind.

REASON FOR ISSUE

On February 8th, 2002, the National Transportation Safety Board (NTSB), in cooperation with the French "Bureau Enquetes Accidents (BEA)", issued recommendations that aircraft manufacturers re-emphasize the structural certification requirements for the rudder and vertical stabilizer, showing how some maneuvers can result in exceeding design limits and even lead to structural failure.
The purpose of this FCOM Bulletin is to re-emphasize proper operational use of the rudder, highlighting certification requirements and rudder control design characteristics.

YAW CONTROL

GENERAL

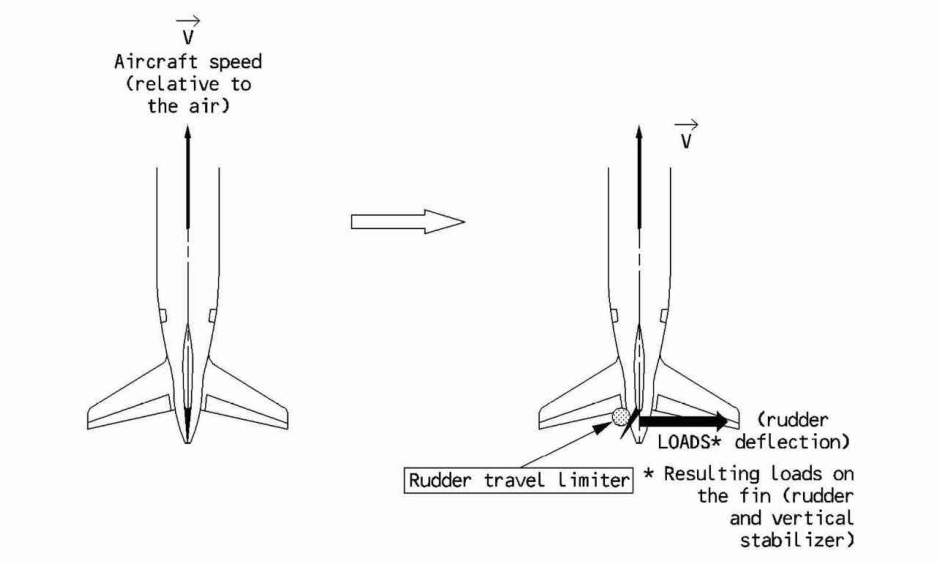
In flight, yaw control is provided by the rudder, and directional stability is provided by the vertical stabilizer.

The rudder and vertical stabilizer are sized to meet the two following objectives:
- Provide sufficient lateral control of the aircraft during crosswind takeoffs and landings, within the published crosswind limits (*Refer to LIM-12 Airport Operations*)
- Provide positive aircraft control under conditions of engine failure and maximum asymmetric thrust, at any speed above VMCG (minimum control speed on ground).

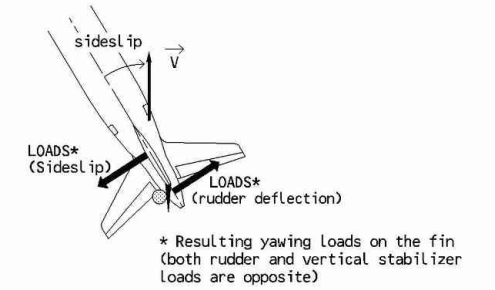
The vertical stabilizer and the rudder must be capable of generating sufficient yawing moments to maintain directional control of the aircraft.
The rudder deflection, necessary to achieve these yawing moments, and the resulting sideslip angles can place significant aerodynamic loads on the rudder and on the vertical stabilizer.
Both vertical stabilizer and rudder are designed to sustain loads as prescribed in the JAR/FAR 25 certification requirements which define several lateral loading conditions (maneuver, gust loads and asymmetrical loads due to engine failure) leading to a required level of structural strength.

CERTIFICATION REQUIREMENTS

For certification in accordance with JAR/FAR 25.351, loads on the stabilizer and the rudder are defined, considering yawing maneuvers as shown below, for a range of speeds from VMC (minimum control speed) to VD/MD (maximum design speed), from sea level up to maximum altitude, and over the full range of aircraft weights and Center of Gravity limits:
1. With the aircraft in unaccelerated and stabilized straight flight, the rudder pedal is suddenly displaced to the maximum available deflection at the current aircraft speed.

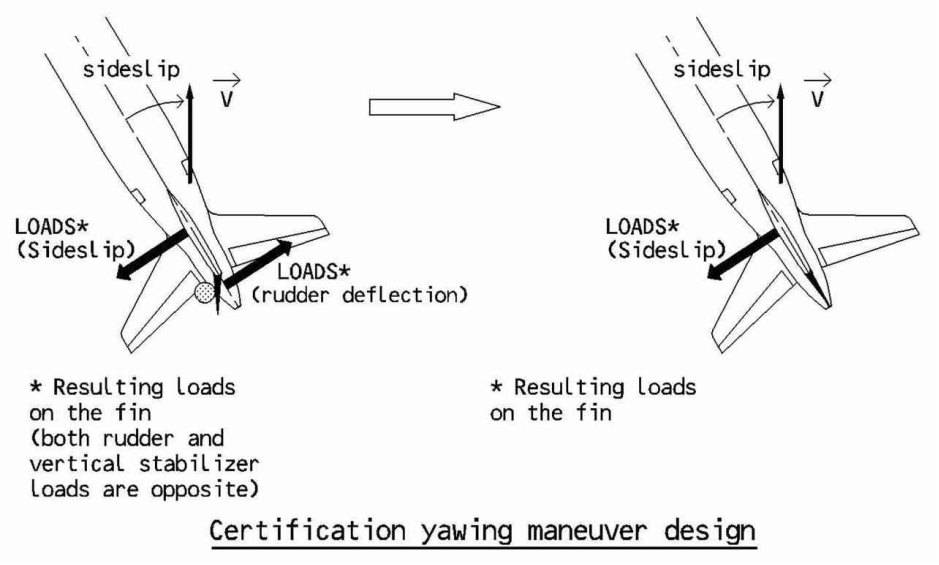


2. With the rudder deflected as shown above, the aircraft yaws to the resulting overswing sideslip angle, and then stabilizes at a somewhat smaller steady-state slideslip angle.



3. With the airplane yawed to the steady-state (static) sideslip angle corresponding to the above rudder deflection, the certification regulations assume that the rudder pedal is released to neutral.

   Note: *Because the aircraft has natural yaw stability, returning the rudder to neutral will also result in returning the sideslip angle to neutral.*



JAR/FAR 25 requires the above yawing maneuver to be analyzed over the full range of specified conditions. The most severe loads imposed on the vertical stabilizer and rudder are identified.

The same analysis is performed for lateral gusts, rolling maneuvers and asymmetrical engine failure conditions. The most severe of all these cases and associated loads provides the design basis for the vertical stabilizer and rudder.

The above loads define the limit loads according to JAR/FAR 25 requirements. These loads correspond to the maximum loads that may be expected in service.

According to JAR/FAR 25 requirements, the ultimate loads are defined as the limit loads multiplied by a prescribed safety factor of 1.5 unless otherwise specified.

The aircraft structure must be able to sustain limit loads without detrimental permanent deformation and ultimate loads without failure for at least 3 s.

Higher loads could lead to structural failure.

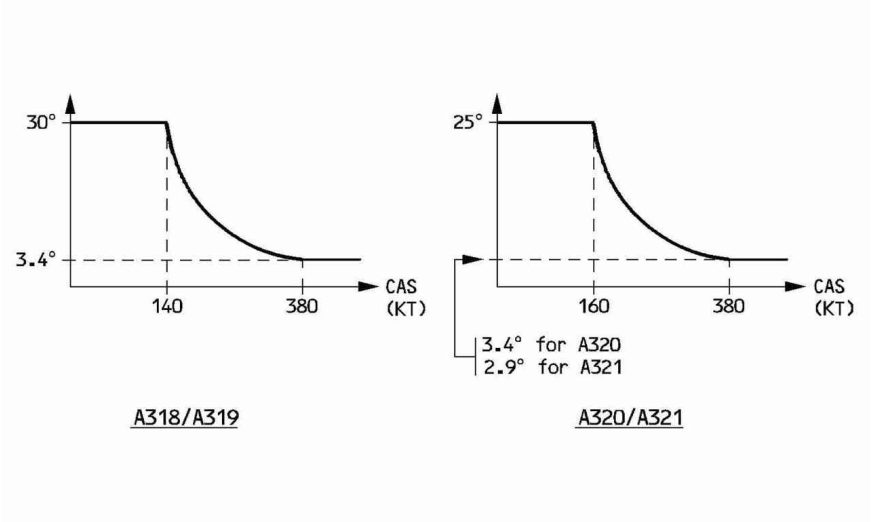
CAUTION	Sudden commanded full, or nearly full, opposite rudder movement against a sideslip can generate loads that exceed the limit loads and possibly the ultimate loads and can result in structural failure. This is true even at speeds below the maximum design maneuvering speed, VA.  Certification regulations do not consider the loads imposed on the structure when there is a sudden full, or nearly full, rudder movement that is opposite to the sideslip.

RUDDER CONTROL

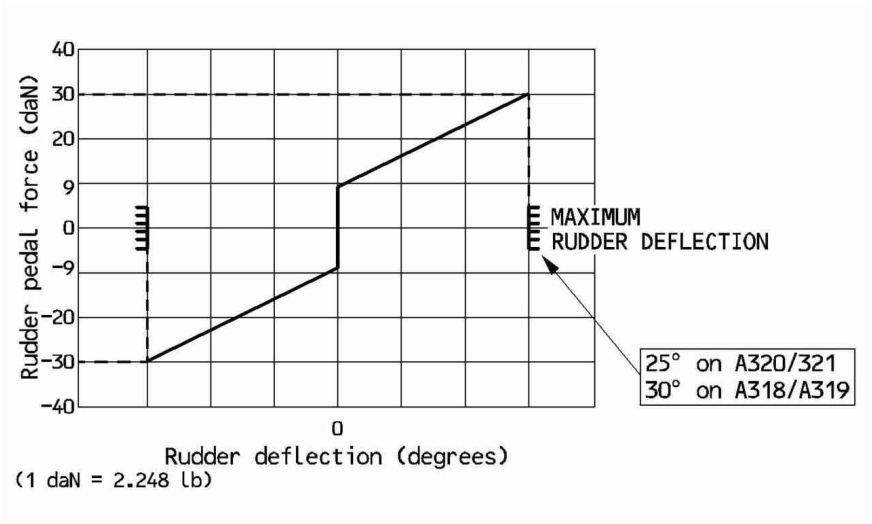
The rudder surface is controlled by 3 actuators, commanded by a cable run from rudder pedals, to which the flight control input (yaw damping and turn coordination functions coming from the ELACs and the FACs) are added.
The rudder travel limiter, controlled by the FACs, is designed to progressively reduce the available total rudder travel depending on aircraft speed.
This provides sufficient yaw control within the entire flight envelope, including engine failure and maximum asymmetric thrust, limiting the lateral loads on the stabilizer and rudder so that they remain within the certification limits.

Rudder travel is limited as a function of the aircraft speed, as shown below:

- At low speeds, the rudder deflection required to maneuver the aircraft in yaw is large, and so are the resulting pedal displacement and forces
- At high speeds, the rudder authority is limited but the gearing between the pedals and the rudder does not change. Therefore, less force will be required to achieve maximum available rudder deflection.



As speed increases, the rudder deflection required by any yaw maneuver (eg, engine failure and maximum asymmetric thrust) decreases, and consequently, so do rudder pedal displacement and associated forces.
Rudder pedal displacement is almost linearly proportional to rudder deflection.



Thus, to explain the two preceding graphs:
The rudder pedal displacement and the resulting pedal forces required to achieve a given rudder deflection are independent from aircraft speed

- To start moving the rudder pedals from the neutral position, a minimum force of ± 9 daN must be applied ("breakout force")
- At low speeds, i.e. up to approximately 150 kt, maximum available rudder deflection (25 ° for the A320/A321 and 30 ° for the A318/A319) is obtained by moving the rudder pedals to their maximum travel which represents a 30 daN force applied on the pedals
- At higher speeds, for example at 350 kt, the maximum available rudder deflection is reduced to approximately 4 °. It is consequently obtained with less rudder pedal displacement which represents approximately a 13 daN force applied on the pedals (approximately 40 % of the maximum force to reach full pedal travel).

OPERATIONAL RECOMMENDATIONS

In order to avoid exceeding structural loads on the rudder and vertical stabilizer, the following recommendations must be observed.

1. The Rudder is Designed to Control the Aircraft, in the Following Circumstances

1.1 In Normal Operations, for Lateral Control:

- During the takeoff roll, when on ground, especially in crosswind conditions
- During landing flare with crosswind, for decrab purposes
- During the landing roll, when on ground.

In these circumstances, large and even rapid rudder inputs may be necessary to maintain control of the aircraft.
Rudder corrections should always be applied as necessary to obtain the appropriate aircraft response.
On Airbus aircraft, the rudder control system includes a turn coordination function to achieve acceptable turn coordination.

1.2 To Counteract Thrust Asymmetry

Full rudder authority can be used to compensate for the yawing moment of asymmetric thrust.

Note: At high speed (i.e. slats retracted), thrust asymmetry (eg. due to an engine failure) has relatively small effect on yaw control of the aircraft.
The amount of rudder required to counter an engine failure and center the sideslip is small.

1.3 In Some Other Abnormal Situations

The rudder may also be used in such abnormal situations as:

- Loss of both yaw damper systems. The rudder may be used as deemed necessary, for turn coordination to prevent excessive sideslip
- Rudder trim runaway. The rudder may be used to return the rudder to neutral
- Landing with abnormal landing gear position. The rudder can be used for directional control on ground.

In all of the above mentioned normal or abnormal circumstances, proper rudder maneuvers will not affect the aircraft's structural integrity.

Note: *In the event of a rudder travel limit system failure, refer to the relevant RUDDER TRAVEL LIMIT FAULT procedure.*

2. The Rudder Should Not be Used

- To induce roll, or
- To counter roll, induced by any type of turbulence.

Whatever the airborne flight condition may be, aggressive, full or nearly full, opposite rudder pedal inputs must not be applied. Such inputs can lead to loads higher than the limit, and can result in structural damage or failure.
The rudder travel limiter system is not designed to prevent structural damage or failure in the event of such rudder system inputs.

Note: *Rudder pedal reversals must never be incorporated into airline policy, including so-called" aircraft defensive maneuvers" to disable or incapacitate hijackers.*

As far as dutch roll is concerned, yaw damper action and natural aircraft damping are sufficient to adequately dampen dutch roll oscillations. The rudder should not be used to complement the yaw damper.

Note: *Even if both yaw damper systems are lost, the rudder should not be used to dampen the dutch roll. Refer to the YAW DAMPER FAULT procedure.*

3. Special Cases

Recovery techniques from upset situations
Proper use of the rudder, particularly during maneuvers intended to address upset recovery, are emphasized in the Airbus Training Program, supported by the industry-produced 1998 "UPSET RECOVERY TRAINING AID".

YAW DISTURBANCES DURING THE TAKEOFF ROLL

Applicable to: ALL

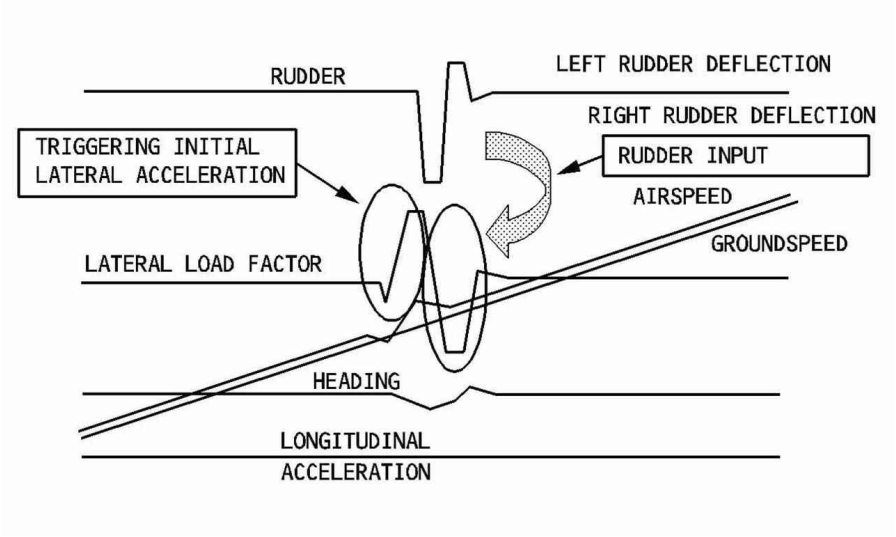
Various operators have reported occurrences of "unusual" yaw movement during the takeoff roll.
The large majority of these events took place in extremely hot weather conditions.
Flight crews have used such terms as "lateral jerk", lateral g-load, or "yaw control perturbation", to describe these occurrences.
Airbus has conducted extensive investigations, in order to fully understand the origin and cause of these events, and to take into account any contributing conditions, whether it be technical or external.

DESCRIPTION OF THE OBSERVED EVENTS

The most significant of these events, included the following characteristics:

- An initial sharp lateral disturbance, associated with short, but substantial, lateral acceleration and heading variation
- In most cases, the pilot took immediate action, with a sharp pedal deflection in the opposite direction, in order to correct the heading and the lateral deviation
- This induced a lateral acceleration peak, of approximately the same magnitude, in the opposite direction.

The general characteristics of these events produce the typical DFDR traces, illustrated below:



ANALYSIS OF THE EVENTS

Simulation tools were specifically developed, in an attempt to reproduce the condition and assess the effects of such failure modes as:

- Sharp rudder deflection (mechanical)
- Sudden differential braking
- Sudden nosewheel movement
- Sudden thrust asymmetry

None of these failure modes could reproduce and explain the typical traces that were observed on the DFDR. This led to the assumption that only external causes were at the root of these events. This assumption was confirmed, after Airbus experienced a similar event on a test aircraft, equipped with a more sophisticated flight test recording equipment (greater sampling rate than the DFDR).

The data recorded onboard the aircraft during this event was used to estimate the profile of a wind variation, which could have generated the recorded lateral disturbance. This was done by two methods, which both led to the same result. It was found that wind profiles, having a magnitude of less than 15 kt, perfectly matched the simulation of the recorded flight parameters.

All of these tests confirmed that the lateral perturbations were not caused by an aircraft system malfunction, but were always due to external lateral gusts.

ORIGIN OF LATERAL GUSTS

Different situations may create isolated lateral gusts. For example, the jet blast of another aircraft close to the active runway, or the wind between two buildings accelerated by "venturi" effect, may create such lateral gust effects. However, the most probable cause is the presence of thermals or thermal vortices that often develop in hot and dry countries. Sometimes, as these thermal streams get stronger, they create small whirlwinds referred to as "dust devils".

AIRCRAFT RESPONSE AND HANDLING

All aircraft can be affected by lateral disturbances and their response, in terms of lateral g, yaw acceleration, and heading variation will depend on the aircraft's aerodynamic characteristics, plus the yaw inertia combined with the dynamics of ground reactions.

Generally speaking, it is easy to maintain the aircraft on the runway centerline via normal use of the rudder. The issue, in these events, is that the disturbance can be quite isolated, and sufficiently strong, to catch the pilot by surprise.

During a takeoff in a gusty crosswind, the pilot may have to cope with the effect of lateral wind variations. In such cases, the pilot will readily control the aircraft on the runway centerline, throughout the takeoff roll, because the aircraft behaves as the pilot expects, and the pilot is prepared to act.

In the reported events, the condition arose suddenly, during the takeoff roll, with very little, or no obvious turbulence. In such circumstances the pilot is less prepared for a such sudden lateral

disturbance; And analysis of these events has revealed that pilots had a tendency to overreact, by increasing rudder input, and consequently increasing the magnitude of the lateral disturbance.

CONCLUSION

The objective of this FCOM Bulletin is to inform flight crews that they may encounter such lateral disturbances, particularly in areas and in weather conditions where strong thermals have a tendency to develop.

Pilots should, therefore, be prepared to react to these isolated disturbances by using the rudder normally, and avoiding excessive rudder input.

AUTOMATIC LANDING PERFORMANCE

Intentionally left blank

FCB-FCB27-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Automatic Landing Performance..... A

Intentionally left blank

AUTOMATIC LANDING PERFORMANCE

Applicable to: ALL

REASON FOR ISSUE

Abnormal automatic landing behaviors are periodically reported on some airports/runways with specific terrain profile before runway threshold, or specific runway profile.

AUTOMATIC LANDING FLARE MODE

All Airbus aircraft use similar FLARE modes for automatic landing. The FLARE mode is initiated at a given radio altitude (RA), which can be either advanced or delayed in function of the Rate Of Descent (ROD) - measured as a rate of change of RA with time.
Once the FLARE mode is engaged, the flare is commenced by an open-loop elevator input (pre-command), which is adapted to the aircraft GW, CG and GS. The flare is then continued with a closed-loop signal to satisfy ROD and RA targets function of the horizontal distance (or time).
The pitch demand given by the flare pre-command is modified by pitch demands in order to reduce the differences between the actual and the desired RA and ROD. The intent is to reduce both the ROD and the RA as a function of distance or time so that the aircraft touches down with a reasonable ROD in a reasonable distance (or time - typically 7 to 9 s).
This is effectively what a pilot does during manual flare. As the ground approaches, pitch-up input is introduced to reduce the ROD; the importance of the input varies according to the pilot's perception of the rate at which the ground is approaching.

AUTOMATIC LANDING CERTIFICATION REQUIREMENTS

The automatic landing certification regulations are complex and impose many requirements on the system. Among performance requirements are limits on touch down vertical speed and touch down distance from runway threshold.

These limits are expressed in term of probability to exceed ultimate values; for touch down vertical speed and distance these limits are:

- The probability to exceed a touch down vertical speed of 10 ft/s must be less than one per million (10^{-6}),
- The probability to touch down at a distance less than 60 m from the runway threshold or more than 900 m must be less than one per million (10^{-6}).

There are similar requirements for the touch down lateral distance from the runway centerline, for the bank angle at touch down and lateral deviation during rollout.
To demonstrate statistically compliance with these requirements, the aircraft manufacturers use a combination of flight tests and simulation tools and must cover the full range of GW, CG and winds in a range of pressure altitude up to the maximum certified altitude for automatic landing (Refer to the AFM).

The automatic landing system performance has been demonstrated during certification with CAT II/III ILS beams with a G/S from 2.5 ° to 3.15 °.
There is no certification requirement to prove that the automatic landing system will perform as expected at all conceivable airports.

Certification flight tests are performed on a limited number of airports equipped with a CAT II or CAT III ILS. However, the simulation tests must include specific unusual terrain profile before runway threshold and specific runway slope:
- Runway slope of ±0.8 % .
- 20 ft step before runway threshold
- Rising terrain slope of 12.5 ° followed by 60 m horizontal surface just before runway threshold.

Airbus aircraft meet all these certification requirements.
In addition, Airbus has assessed in simulation the effect of terrain/runway profiles of specific airports known to be somehow problematic ("special terrain/runway profile").
The appendix 8 of FAA AC 120-280 related to irregular terrain assessment as part of the CAT III operational evaluation gives the following background: "FAA type design approval of flight guidance systems provides for generic performance evaluation of autoland capability through simulation with reference terrain conditions, and flight testing at a few particular locations. This is to verify suitability of the design analysis. When an aircraft is type certificated for use of a flight guidance system, it is not the intent, nor is it practical that each model of aircraft be tested at each conceivable locations that it could potentially be used in operations ... While type design certification addresses generic system performance, specific operational review and approval of particular aircraft type/site autoland performance is necessary when minima are predicated on the use of autoland. This is especially important at airports with irregular pre-threshold terrain (e.g., cliffs, valleys, sea walls) in the area of final approach within approximately 1 500 ft of runway threshold."

AUTOMATIC LANDING DISTANCE

The automatic landing distance calculation uses a realistic airborne distance obtained from flight tests demonstrations - statistically determined as the mean touch down distance from runway threshold plus 3 times the standard variation of this distance -, which is then added to a ground distance calculated with maximum braking starting at the mean touchdown speed plus 3 times the standard variation of this speed. The combined airborne and ground distances are then multiplied by 1.15 to give the automatic landing distance. Refer to QRH Autoland.
The required landing distance cannot be less than the manual landing distance multiplied by 1.67 (or 1.67 x 1.15 on wet runway) or the automatic landing distance, whichever is the highest.
The airborne mean distance and its statistical variation is determined using data collected for the certification process. A special runway profile (for example hill top double slope) may lead to increase airborne distances.

EFFECT OF TERRAIN/RUNWAY PROFILE

A higher ROD in the last part of the approach (due to terrain profile before runway threshold) will cause the flare mode to engage earlier than usual.
A rising slope before the runway can cause the flare to engage higher, and the aircraft may temporarily float above the runway surface before the pitch is reduced to resume a gentle descent down to the runway leading to a long flare. If, in addition, the runway has a negative slope, the descent will be further prolonged. However, the system will always try to re-establish the aircraft on the flare profile.
In general, runways sloping up are prone to produce firm landings whereas runways sloping down will tend to produce long flares.
Double runway slope with hill top located in the touch down zone may significantly affect the statistical distribution of the touch down point, increasing sometimes the airborne distance.
A flare is a dynamic maneuver, and flares are never exactly the same. To satisfy certification requirements, the RA signal is filtered to avoid irregular variations, and the aircraft reaction in pitch is limited in order to prevent over-reactions in the event of erroneous signal variations. The consequence of these requirements is a more sluggish response to variations in RA signal, which restricts the ability to cope with large variations in terrain/runway profile.

OPERATIONAL DEMONSTRATION

For the purpose of CAT II/III operational demonstration, the airline has to perform a number of automatic landings in good weather conditions on different runways, usually at their home base and main destinations.

To determine if an airport/runway is eligible for CAT II/III operations, the Appendix 1 of JAR OPS 1.440 (h) requires that:

1. "Each aeroplane type/on-board equipment/runway combination must be verified by the completion of at least one approach and landing in Category II or better weather conditions, prior to commencing Category III operations.
2. For runways with irregular pre-threshold terrain or other foreseeable or known deficiencies, each aeroplane type/on-board equipment/runway combination must be verified by operations in Category I or better weather conditions, prior to commencing Category II or III operations".

The appendix 8 of FAA AC 120-280 says: "At typical airports runways that are not considered to be "special terrain", the review and approval process usually consists of verifying the operator's report or performance for a small number of "line landings" using the flight guidance system in weather conditions better than those requiring use of CAT II or lower minima".
Before deciding that an airport/runway is suitable for automatic landing, the operator must seek information on the local characteristics of the runway and verify that the airport is not listed as "special terrain" for CAT II/III operations (e.g., those listed for example in the CAT II/III Status on the FAA web site).

For airports/runways that exhibit special characteristics (pre-threshold terrain, runway profile or a combination of both), a specific operational evaluation is generally necessary. This initial evaluation should consist in 4 to 6 automatic landings in typical wind conditions and representative LW to be performed by a CAT III qualified and experienced pilot (Airline technical pilot, senior training pilot, ...).
DFDR data need to be analyzed to verify that the automatic landing system performed adequately. Airbus may support the operator for this data analysis. This initial evaluation should be then complemented by the monitoring of typically 25 automatic landings in line operation.
This evaluation program should be done with the agreement of the operational authorities using for example the guidelines from FAA AC 120-280 Appendix 8.

AUTOMATIC LANDING IN CAT I OR BETTER WEATHER CONDITIONS

Automatic landings need sometimes to be performed in CAT I or better weather conditions for flight crew training purpose or for operational evaluation/demonstration.

Although the automatic landing system performance has been demonstrated during certification with CAT II/III ILS beams, automatic landing is possible on a CAT I ILS, or on a CAT II/III ILS when the ILS protection is not activated (Low Visibility Procedure not enforced), provided:

- The operator has checked that the ILS beam quality and the effect of the terrain profile before the runway have no adverse effect on autopilot guidance. For that, the operator should seek information on terrain discontinuities before runway threshold and runway slope. Information from other operators with the same aircraft type and airport authorities can also be used.
- The flight crew is aware that LOC or G/S beam fluctuations independent of the aircraft system may occur, and the PF is prepared to immediately disconnect the AP and to take the appropriate action, should unsatisfactory guidance occur.

AUTOMATIC ROLLOUT ON CAT II RUNWAYS

For CAT II operations there is no requirement on LOC beam quality for the rollout segment. Automatic rollout in CAT II operations on a runway that is not CAT III qualified remains under the crew responsibility.

- As LOC beam fluctuations independent of the aircraft system may occur, the PF should be prepared to take over directional control if the AP disconnects during rollout, or to immediately disconnect the AP if unsatisfactory rollout guidance occurs.

AUTOMATIC LANDING ABOVE MLW

For some Airbus models, the FCOM OVERWEIGHT LANDING procedure may indicate that automatic landing is certified up to the MLW but that flight tests have been performed successfully up to a higher LW. The FCOM states that in case of emergency, and under crew responsibility, an automatic landing may be performed up to this higher LW, provided the runway is approved for automatic landing.

This means that Airbus has performed a number of automatic landings up to this higher LW for average conditions in term of CG, wind, and runway characteristics. The full range of conditions required by the certification requirements have not been assessed for LW higher than the MLW. However, the tests performed are sufficient to indicate that the possibility of an automatic landing is an option that the flight crew can consider in its decision making resulting from an emergency in particular operational situation.

AUTOMATIC LANDING WITH OUT-OF-DATE ADIRS MAG VAR TABLE

Some Airbus SA and LR aircraft continue to fly a number of years with ADIRS part numbers fitted with out-of-date magnetic variation tables. If the ADIRS magnetic variation differs by more than 2 ° or 3 ° (depending of aircraft type) compared to the airport current magnetic variation, the lateral performance of the automatic landing and rollout is significantly affected, which prevents from using the automatic landing system on these airports. Airbus publishes in the FCOM for each year, the list of airports where automatic landing is no more authorized with these ADIRS part numbers.

AIRPORTS/RUNWAYS WITH "SPECIAL TERRAIN/RUNWAY PROFILE"

The consequences of irregular terrain or runway profile on the automatic landing system performance can be quite variable.
For example, the automatic landing RW 03 R in Johannesburg (JNB) had to be suspended for the Airbus SA until certification of a new standard of FMCG (refer to FCOM Limitation).
Another example is RW 32 in Leeds (LBA) also with Airbus SA where the consequence of the runway profile is only a possibility of long flare. In this case an increase of the automatic landing distance of 300 m is sufficient to address the runway specificity.

DEFINITIONS

Applicable to: ALL

MANUFACTURER'S EMPTY WEIGHT (MEW)

The weight of the structure, power plant, furnishings, systems and other items of equipment that are considered as integral part of the aircraft. It is essentially a "dry" weight, including only those fluids contained in closed systems (e.g. hydraulic fluid).

OPERATIONAL EMPTY WEIGHT (OEW)

The manufacturer's weight empty plus the operator's items i.e. the flight and cabin crew and their baggage, unusable fuel, engine oil, emergency equipment, toilet chemicals and fluids, galley structure, catering equipment, seats, documents etc.

DRY OPERATING WEIGHT (DOW)

The total weight of an aircraft ready for a specific type of operation excluding all usable fuel and traffic load.
Operational Empty Weight plus items specific to the type of flight i.e. catering, newspapers, pantry equipment etc.

TAKEOFF FUEL

The weight of the fuel onboard at takeoff.

OPERATING WEIGHT

The weight obtained by addition of the operational empty weight and the takeoff fuel.

TOTAL TRAFFIC LOAD

The weight of the payload including cargo loads, passengers and passengers bags.

ZERO FUEL WEIGHT (ZFW)

The weight obtained by addition of the total traffic load and the dry operating weight.

TAKEOFF WEIGHT (TOW)

The weight at takeoff. It is equal to the addition of the zero fuel weight and takeoff fuel.

TRIP FUEL

The weight of the fuel necessary to cover the normal leg without reserves.

LANDING WEIGHT

The weight at landing. It is equal to takeoff weight minus trip fuel.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Each compartment is divided into sections, and is designed to be category D (for A320 and A319) or category C (A321, A319 ◁ and A320 ◁) as defined by FAR.
A placard in each compartment indicates the maximum authorized gross weight.
The compartments have separate lighting.

DESCRIPTION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Each compartment is divided into sections, and is designed to be category C as defined by FAR.
A placard in each compartment indicates the maximum authorized gross weight.
The compartments have separate lighting.

RESTRAINT SYSTEM

Applicable to: ALL

Divider nets subdivide the compartments to allow them to be partially loaded and to retain the bulk.
Door nets which protect the doors from shifting cargo, must be used whenever the compartment contain cargo.

CARGO LOADING SYSTEM (IF INSTALLED)

Applicable to: ALL

A semi-automatic cargo loading system, which may be installed in forward and aft compartments, loads pallets and containers.

CARGO CAPACITY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

FULL BULK

The maximum load capacity for each cargo compartment is as follows :

- **Forward**
  - Compartment 1 : 3 402 kg (7 500 lb)
- **Aft**
  - Compartment 3 : 2 426 kg (5 349 lb)
  - Compartment 4 : 2 110 kg (4 652 lb)
  - Compartment 5 : 1 497 kg (3 300 lb)

CARGO CAPACITY

Applicable to: B-HTG, B-HTH, B-HTI

FULL BULK

The maximum load capacity for each cargo compartment is as follows :

- **Forward**
  Compartment 1 : 2 202 kg (4 854 lb)
  Compartment 2 : 3 468 kg (7 645 lb)
- **Aft**
  The following table indicates the maximum allowable cargo load (fuel excluded) for each aft cargo compartment, and the maximum allowable combined load (cargo + ACT fuel) for all aft cargo compartments. Both sets of limitations must be respected.

	Maximum Gross Weight		
	ACT not installed	**One ACT installed**	**Two ACTs installed**
Compartment 3 (cargo)	3 587 kg (7 908 lb)	2 298 kg (5 067 lb)	1 121 kg (2 472 lb)
Compartment 4 (cargo)	2 083 kg (4 592 lb)	2 083 kg (4 592 lb)	2 083 kg (4 592 lb)
Compartment 5 (cargo)	1 497 kg (3 300 lb)	1 497 kg (3 300 lb)	1 497 kg (3 300 lb)
Compartments 3+4+5 (cargo + ACT fuel)	Not applicable	7 298 kg (16 089 lb)	6 924 kg (15 264 lb)

The yellow hydraulic system is pressurized (YELLOW ELEC PUMP energized). Operation of the flight controls and PTU is inhibited.

- **When the door is fully open (green light on the service panel is on) :**
  LEVER OF MANUAL SELECTOR VALVE.....RELEASE

  When released, the lever returns to the neutral position and shuts down the electric pump.

CLOSING

- **On door service panel**
  LEVER OF MANUAL SELECTOR VALVE.....HOLD ON CLOSE

  At first the lever locks in an intermediate position, maintaining a pre-set pressurization to prevent the door from dropping open. The operator can then move the lever to CLOSE and the door closes. When it is fully closed, the lever returns to the neutral position and shuts down the electric pump.
  Ensure that green indicator light goes off.

- **On door**
  DOOR..... LOCK

  Immediately push the door operating handle upwards to the locked position. When the door is locked, the cargo doors view ports appear green, the CARGO door indication on ECAM extinguishes, and the handle flap mechanism locks the operating handle.

- **On door service panel**
  ACCESS DOOR.....CLOSE

AUXILIARY OPERATION

In case of an electrical failure or if the electric pump fails, the operator can open or close the doors by working the hand pump.

HAND PUMP OPENING

- **On door**
  DOOR..... UNLOCK

  Unlock the operating handle as if for normal operation.

- **On door service panel**
  SERVICE PANEL ACCESS DOOR.....OPEN
  LEVER OF MANUAL SELECTOR VALVE.....HOLD ON OPEN

- **On ground service panel**
  HAND PUMP.....OPERATE
  The door opens.

- **When the door is fully open (green light on the service panel is on) :**
  - **On door service panel**
    LEVER OF MANUAL SELECTOR VALVE..... RELEASE

HAND PUMP CLOSING

- **On door service panel**
  LEVER OF MANUAL SELECTOR VALVE.....HOLD ON CLOSE
- **On ground service panel**
  HAND PUMP.....OPERATE
  The door closes.
- **On door service panel**
  LEVER OF MANUAL SELECTOR VALVE.....RELEASE
  Release when door is fully closed.
- **On door**
  DOOR..... LOCK
  Lock the operating handle as for normal operation.
- **On door service panel and ground service panel**
  ACCESS DOORS.....CLOSE

REFUELING

- During automatic refueling, fuel goes into the center tank and outer cell of wing tanks simultaneously. When the outer cell the wing tank is full, fuel overflows into the inner cell. During manual refueling, fill the wing tanks first, then the center tank.
- With the tanks filled to the maximum capacity, there is enough space in each tank to allow for a 2 % thermal expansion of the fuel without its spilling through the vent system.
- Electrical transients (caused by switching among the APU, the external and the engine electrical supply) during automatic refueling may stop the process. If the automatic refueling process is stopped, it is necessary to re-enter the Preselected Fuel Quantity.

Applicable to: B-HTD, B-HTE, B-HTF

REFUELING

PREPARATION

ACCESS PLATFORM.....IN POSITION

SAFETY PRECAUTIONS.....APPLY

During refueling operations, ensure that:
- *No HF transmission is performed*
- *The aircraft is properly bonded to the tanker*
- *The tanker and the aircraft are properly grounded. If suitable ground is not available, the aircraft can be bonded to the tanker only. Always connect the ground cable to the parking ground point (or to the tanker) before connecting it to the aircraft. In the cockpit, check that the PARK BRK is ON and that the ACCU PRESS has sufficient pressure. Do not refuel, if a fire or engine overheat warning is displayed. During refueling, do not operate the external lighting.*

.

Note: For APU start/shutdown during refueling, Refer to PER-LOD-FUL APU START/SHUTDOWN DURING REFUELING/DEFUELING.

MAX REFUELING PRESSURE.....50 PSI (3.5 bar)

● **On refueling control panel:**

TEST..... LTS

Lights on the panel come on. FUEL QTY and the PRESELECTED and ACTUAL displays show 8's.

TEST.....HI.LVL

HI LVL lights change state if the high level sensors and their circuits are serviceable.

AUTOMATIC REFUELING

REFUEL VALVES.....CHECK NORM and GUARDED
PRESELECTOR.....SET
MODE SELECT..... REFUEL
START REFUELING

When the refueling is finished the END light comes on.

ACTUAL QUANTITY..... CHECK

The actual quantity must be within 100 kg (220 lb) of the preselected quantity.

MODE SELECT.....OFF and GUARDED

MANUAL REFUELING

REFUEL VALVES..... SHUT
MODE SELECT..... REFUEL
REFUEL VALVES (tanks to be filled)..... OPEN
START REFUELING

FUEL QTY.....MONITOR

- **When the contents of the tanks reach the required level :**

  Corresponding REFUEL VALVES.....SHUT
  MODE SELECT.....OFF and GUARDED
  REFUEL VALVES.....NORM and GUARDED

GROUND FUEL TRANSFER

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- **On cockpit overhead FUEL panel**

  PUMPS (of the tanks not to be defueled).....OFF
  MODE SEL.....MAN
  PUMPS (of the tank to be defueled).....ON

- **if left wing and/or center tanks is (are) to be defueled :**

  X FEED.....ON

  OPEN light comes on.

- **On refueling control panel :**

  REFUEL VALVES (of tanks not to be filled).....SHUT
  REFUEL VALVES (of tanks to be filled).....OPEN
  MODE SELECT.....DEFUEL/XFR

  OPEN light comes on.

  FUEL QTY.....MONITOR

- **When the tank contents reach the required level :**

  Corresponding REFUEL VALVES.....SHUT
  MODE SELECT.....OFF and GUARDED

  OPEN light goes out.

  REFUEL VALVES.....NORM and GUARDED

  Set cockpit FUEL panel to normal configuration.

GROUND FUEL TRANSFER

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- **From one wing tank to the other wing tank or to the center tank :**

  - **On cockpit overhead FUEL panel**

    PUMPS (of the wing tank not to be defueled).....OFF
    PUMPS (of the wing tank to be defueled).....ON

X FEED.....ON

OPEN light comes on.

- **On refueling control panel :**

REFUEL VALVES (of tanks not to be filled)..... SHUT
REFUEL VALVES (of tanks to be filled)..... OPEN
MODE SELECT.....DEFUEL/XFR

OPEN light comes on.

FUEL QTY..... MONITOR

- **When the tank contents reach the required level :**

Corresponding REFUEL VALVES.....SHUT
MODE SELECT..... OFF and GUARDED

OPEN light goes out.

REFUEL VALVES.....NORM and GUARDED

Set cockpit FUEL panel to normal configuration.

- **From center tank to the L (R) wing tank :**

L(R) TK PUMPS..... ON
CTR TK L(R) XFR..... ON

When the wing tank is full or if the center tank is empty the transfer valve will automatically close.

- **From ACT to center tank :**
  - **On cockpit refuelling control panel (if fitted) :**

REFUEL PWR pushbutton switch.....ON

or

REFUEL/DEFUEL Control panel access door..... OPEN

  - **On cockpit overhead FUEL panel**

ACT.....FWD
FUEL QTY..... MONITOR

  - **When the tank contents reach the required level :**

ACT..... AUTO
REFUEL PWR Pushbutton switch.....OFF

or

REFUEL/DEFUEL control panel access door.....CLOSE

DEFUELING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Note: Defueling by suction is not possible

ACCESS PLATFORM.....IN POSITION
SAFETY PRECAUTIONS.....APPLY

During defueling operations, ensure that:
- *No HF transmission is performed*
- *The aircraft is properly bonded to the tanker*
- *The tanker and the aircraft are properly grounded. If suitable ground is not available, the aircraft can be bonded to the tanker only. Always connect the ground cable to the parking ground point (or to the tanker) before connecting it to the aircraft. In the cockpit, check that the PARK BRK is ON and that the ACCU PRESS has sufficient pressure. Do not defuel, if a fire or engine overheat warning is displayed. During defueling, do not operate the external lighting.*

Note: For APU start/shutdown during defueling, Refer to PER-LOD-FUL APU START/SHUTDOWN DURING REFUELING/DEFUELING.

MAX DEFUELING PRESSURE.....11 PSI (0.75 bar)

- **On cockpit overhead FUEL panel:**
  PUMPS.....OFF
- **On refueling control panel:**
  REFUEL VALVES.....NORM
  MODE SELECT (OPEN light comes on).....DEFUEL/XFR
- **On cockpit overhead FUEL panel :**
  MODE SEL.....MAN
  PUMPS (of the tank(s) to be defueled).....ON
  X FEED (OPEN light comes on).....ON
  FUEL QTY.....MONITOR
- **When tank contents reach required level**
  Corresponding PUMPS.....OFF
- **On refueling control panel:**
  MODE SELECT (OPEN light goes out).....OFF and GUARDED
  REFUEL VALVES.....NORM and GUARDED

  Set cockpit FUEL panel to normal configuration.

DEFUELING

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Note: *Defueling by suction is not possible. Fuel can be removed from wing tank only. To defuel center tank, first transfer fuel to the wing tanks.*

ACCESS PLATFORM.....IN POSITION
SAFETY PRECAUTIONS.....APPLY

During defueling operations, ensure that:
- *No HF transmission is performed*
- *The aircraft is properly bonded to the tanker*
- *The tanker and the aircraft are properly grounded. If suitable ground is not available, the aircraft can be bonded to the tanker only. Always connect the ground cable to the parking ground point (or to the tanker) before connecting it to the aircraft. In the cockpit, check that the PARK BRK is ON and that the ACCU PRESS has sufficient pressure. Do not defuel, if a fire or engine overheat warning is displayed. During defueling, do not operate the external lighting.*

Note: *For APU start/shutdown during defueling, Refer to PER-LOD-FUL APU START/SHUTDOWN DURING REFUELING/DEFUELING.*

MAX DEFUELING PRESSURE.....11 PSI (0.75 bar)

- **On cockpit overhead FUEL panel:**
  PUMPS.....OFF
- **On refueling control panel:**
  REFUEL VALVES.....NORM
  MODE SELECT (OPEN light comes on).....DEFUEL/XFR
- **On cockpit overhead FUEL panel :**
  PUMPS (of the tank(s) to be defueled).....ON
  X FEED (OPEN light comes on).....ON
  FUEL QTY.....MONITOR
- **When tank contents reach required level**
  Corresponding PUMPS.....OFF
- **On refueling control panel:**
  MODE SELECT (OPEN light goes out).....OFF and GUARDED
  REFUEL VALVES.....NORM and GUARDED

  Set cockpit FUEL panel to normal configuration.

OVERWING GRAVITY REFUELING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Overwing gravity refueling is done at the refuel point in the top of each wing. Fuel is delivered directly into the outer cell from which the inner cell is filled by opening the intercell transfer valves. Fill center tank by transfer from the right wing tank (open the X FEED valve in case of transfer from the left wing tank).

SAFETY PRECAUTIONS.....APPLY

Disembark all passengers.

During refueling operations, ensure that:
- *No HF transmission is performed*
- *The aircraft is properly bonded to the tanker*
- *The tanker and the aircraft are properly grounded. If suitable ground is not available, the aircraft can be bonded to the tanker only. Always connect the ground cable to the parking ground point (or to the tanker) before connecting it to the aircraft. Refer to Aircraft Maintenance Manual (AMM) 12–11–28 PB 301 for detailed safety procedures.*

Note: *For APU start/shutdown during refueling, Refer to PER-LOD-FUL APU START/SHUTDOWN DURING REFUELING/DEFUELING.*

TRANSFER VALVES (on ECAM FUEL page)..... CHECK POSITION

- **If transfer valves closed:**

  MODE SELECT (on the refuel control panel)..... Check OFF

  FUEL/XFR VALVE 1/WING/L C/B (A10 on 49VU) and FUEL/XFR VALVE 2/WING/L C/B (M22 on 121VU)..... PULL for a minimum of 5 s then PUSH

  The refuel control panel door must be closed when the C/B's are being pulled.

  FUEL/XFR VALVE 1/WING/R C/B (A11 on 49VU) and FUEL/XFR VALVE 2/WING/R C/B (M23 on 121VU)..... PULL for a minimum of 5 s then PUSH

  Intercell transfer valves will stay open until the next refuel selection.

FUEL/XFR VALVE 1/WING/L and R C/B's (A10 and A11 on 49VU), and FUEL/XFR VALVE 2/WING/L and R C/B's (M22 and M23 on 121 VU).....PULL

The refuel control panel door must be closed when the C/B's are being pulled. Then it could be opened for subsequent procedures.

RH WING REFUELING PROCEDURE

* OVERWING REFUEL CAP.....REMOVE

* REFUELING..... START

- **If the center tank is to be refueled:**

  GROUND FUEL TRANSFER PROCEDURE..... APPLY

● **When the wing tank reaches the required level:**
* REFUELING.....STOP
* OVERWING REFUEL CAP..... INSTALL

LH WING REFUELING PROCEDURE

Perform the steps for RH wing refueling procedure marked * then:

FUEL/XFR VALVE 1/WING/L and R C/B's (A10 and A11 on 49VU) and FUEL/XFR VALVE 2/WING/L and R C/B's (M22 and M23 on 121VU)..... PUSH
MODE SELECT..... REFUEL then OFF

Check on FUEL page that the intercell transfer valves close.

Note: *The overwing refuel point is not at the highest point of the wing and therefore the wing tanks cannot be filled to full.*

OVERWING GRAVITY REFUELING

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Overwing gravity refueling is done at the refuel point in the top of each wing. Fill center tank by transfer from the right wing tank (open the X FEED valve in case of transfer from the left wing tank) and ACT by transfer from the center tank.

SAFETY PRECAUTIONS.....APPLY

Disembark all passengers.

During refueling operations, ensure that:
- *No HF transmission is performed*
- *The aircraft is properly bonded to the tanker*
- *The tanker and the aircraft are properly grounded. If suitable ground is not available, the aircraft can be bonded to the tanker only. Always connect the ground cable to the parking ground point (or to the tanker) before connecting it to the aircraft. Refer to Aircraft Maintenance Manual (AMM) 12–11–28 PB 301 for detailed safety procedures.*

Note: *For APU start/shutdown during refueling, Refer to PER-LOD-FUL APU START/SHUTDOWN DURING REFUELING/DEFUELING.*

RH WING REFUELING PROCEDURE

* OVERWING REFUEL CAP.....REMOVE
* REFUELING..... START

● **If the center tank and/or the ACTs are to be refueled:**
GROUND FUEL TRANSFER PROCEDURE..... APPLY

- **When the wing tank reaches the required level:**
  - * REFUELING.....STOP
  - * OVERWING REFUEL CAP..... INSTALL

LH WING REFUELING PROCEDURE

Perform the steps for RH wing refueling procedure marked * then:

MODE SELECT..... REFUEL then OFF

Note: The overwing refuel point is not at the highest point of the wing and therefore the wing tanks cannot be filled to full.

REFUELING WITH ONE ENGINE RUNNING

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- Refuel with one engine running only at airports where no external ground pneumatic power is available and only when APU is unserviceable.
- Only the RH fuel couplings can be used.
- Overwing gravity filling is not permitted.
- Disembark all passengers.
- Obtain airport authorization.
  The Airport Fire Department should standby at the aircraft during the entire refueling procedure.
- Point the aircraft into the wind at a location where the slope is negligible.
  Set the parking brake and check its pressure.
  Run engine n° 1 at ground idle with its generator connected.
- Do not start engine n° 2, shut down engine n° 1 or attempt to start the APU before all fueling operations have been completed.
- Position the fuel truck under the extremity of the right wing. Its pressure should not exceed 30 PSI.
- Follow manual refueling procedure.

OPERATION MONITORING

DURING THE ENTIRE REFUELING PROCEDURE :

- Monitor the fuel truck shut off valve.
- Be sure that the fueling company is keeping permanent control of the emergency fuel shut off device.
- Have a flight crew member in the cockpit monitoring all systems and the running engine.

- Have a qualified ground crew member at the fueling station to operate the refuel valve switches.
- Monitor the refueling closely and be prepared to close the refuel valves in order not to exceed the following fuel quantities :

DENSITY (kg/l)	0.77	0.78	0.79	0.8	0.81	0.82	0.83
L(R) WING (kg)	5 710	5 780	5 860	5 930	6 005	6 080	6 160
CENTER (kg)	6 030	6 110	6 190	6 270	6 350	6 430	6 500

AFTER SECOND ENGINE START :

- **Reset the 3DMCs in order to reinitialize the fuel used values :**

  DMC 1 SPLY C/B (E11 on 49VU)..... PULL
  DMC 2 SPLY C/B (Q8 on 121 VU).....PULL
  DMC 3 SPLY C/B (Q9 on 121 VU).....PULL
  DMC 3 SPLY STBY (E10 on 49 VU).....PULL

  - **After 5 s :**

    All C/B's.....PUSH

    Note: *The T.O MEMO does not appear automatically since one engine is kept running.*

REFUELING WITH ONE ENGINE RUNNING

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- Refuel with one engine running only at airports where no external ground pneumatic power is available and only when APU is unserviceable.
- Only the RH fuel couplings can be used.
- Overwing gravity filling is not permitted.
- Disembark all passengers.
- Obtain airport authorization.
  The Airport Fire Department should standby at the aircraft during the entire refueling procedure.
- Point the aircraft into the wind at a location where the slope is negligible.
  Set the parking brake and check its pressure.
  Run engine n° 1 at ground idle with its generator connected.
- Do not start engine n° 2, shut down engine n° 1 or attempt to start the APU before all fueling operations have been completed.
- Position the fuel truck under the extremity of the right wing. Its pressure should not exceed 30 PSI.
- Follow manual refueling procedure.

OPERATION MONITORING

DURING THE ENTIRE REFUELING PROCEDURE :

- Monitor the fuel truck shut off valve.
- Be sure that the fueling company is keeping permanent control of the emergency fuel shut off device.
- Have a flight crew member in the cockpit monitoring all systems and the running engine.
- Have a qualified ground crew member at the fueling station to operate the refuel valve switches.
- Monitor the refueling closely and be prepared to close the refuel valves in order not to exceed the following fuel quantities :

DENSITY (kg/l)	0.77	0.78	0.79	0.8	0.81	0.82	0.83
L(R) WING (kg)	5 660	5 730	5 810	5 880	5 950	6 030	6 100
CENTER (kg)	5 990	6 070	6 150	6 220	6 300	6 380	6 460

AFTER SECOND ENGINE START :

- **Reset the 3DMCs in order to reinitialize the fuel used values :**

  DMC 1 SPLY C/B (E11 on 49VU)..... PULL
  DMC 2 SPLY C/B (Q8 on 121 VU).....PULL
  DMC 3 SPLY C/B (Q9 on 121 VU).....PULL
  DMC 3 SPLY STBY (E10 on 49 VU).....PULL

  - **After 5 s :**

    All C/B's.....PUSH

    Note: *The T.O MEMO does not appear automatically since one engine is kept running.*

APU START/SHUTDOWN DURING REFUELING/DEFUELING

Applicable to: ALL

APU starts or shutdowns are permitted during refuel/defuel procedures. If it is necessary to operate the APU, the limits that follow apply :

a. An APU start is not permitted during a refuel/defuel procedure if the APU has failed to start or an automatic shutdown has occured
b. A normal APU shutdown must be completed if a fuel spill has occured during the refuel defuel procedure.

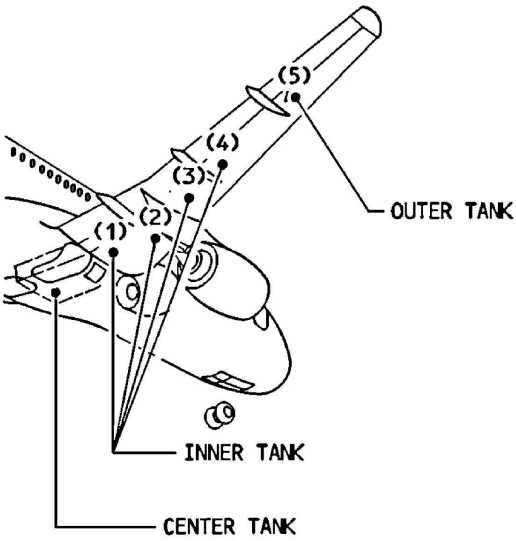
USE OF MANUAL MAGNETIC INDICATORS (MMI)

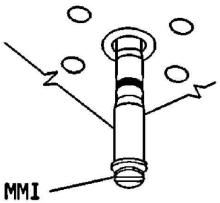
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN

GENERAL

Indicators are disposed as follows:

- five in each wing tank, four in inner tank and one in outer tank
- one in the center tank





TO DETERMINE AIRCRAFT ATTITUDE

Set ADIRS 1, 2, 3 to the NAV position.
On the LH or RH MCDU, press MCDU MENU pushbutton.
Select CFDSline key (LSK 4L).
Select SYSTEM REPORT/TEST line key (LSK 5L).
Select the line key adjacent to the FUEL indication.
On the MCDU control panel, push the NEXT PAGE key to display the FUEL Main Menu second page.
Select the line key adjacent to the INPUT PARAMETERS VALUES indication.
Use the Table given on the next page to determine the equivalent number and letter from PITCH and ROLL data.
Select RETURN line key (LSK 6L) until CFDS main menu appears.
Press MCDU MENU pushbutton.

PITCH	REF	ROLL	REF
Minus 1.5	1	**Minus 1.5**	A
Minus 1.0	2	**Minus 1.0**	B
Minus 0.5	3	**Minus 0.5**	C
0.0	4	**0.0**	D
Plus 0.5	5	**Plus 0.5**	E
Plus 1.0	6	**Plus 1.0**	F
Plus 1.5	7	**Plus 1.5**	G

Note: *1. This procedure can only be used if:*

- *The PITCH and ROLL data is taken from the ADIRS (identified by an "A" after the PITCH and ROLL title).*
- *The PITCH data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*
- *The ROLL data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*

2. The FQIS input parameters are not automatically updated. Use the NEXT PAGE control on the MCDU to cycle the pages to update the screen.

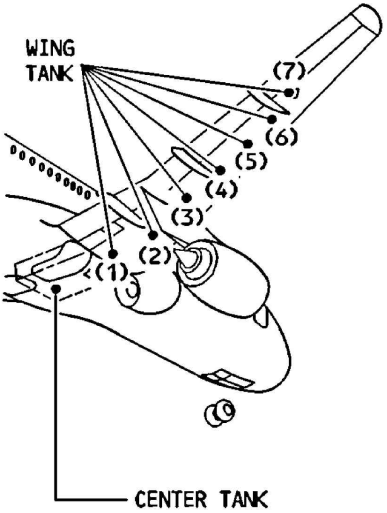
ACCESS PLATFORM.....IN POSITION

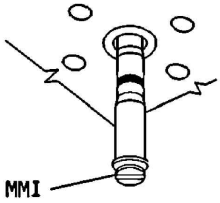
Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

GENERAL

Indicators are disposed as follows :

- seven in each wing tank,
- one in the center tank





TO DETERMINE AIRCRAFT ATTITUDE

Set ADIRS 1, 2, 3 to the NAV position.
On the LH or RH MCDU, press MCDU MENU pushbutton.
Select CFDSline key (LSK 4L).
Select SYSTEM REPORT/TEST line key (LSK 5L).
Select the line key adjacent to the FUEL indication.
On the MCDU control panel, push the NEXT PAGE key to display the FUEL Main Menu second page.
Select the line key adjacent to the INPUT PARAMETERS VALUES indication.
Use the Table given on the next page to determine the equivalent number and letter from PITCH and ROLL data.
Select RETURN line key (LSK 6L) until CFDS main menu appears.
Press MCDU MENU pushbutton.

PITCH	REF	ROLL	REF
Minus 1.5	1	**Minus 1.5**	A
Minus 1.0	2	**Minus 1.0**	B
Minus 0.5	3	**Minus 0.5**	C
0.0	4	**0.0**	D
Plus 0.5	5	**Plus 0.5**	E

Continued on the following page

Continued from the previous page

PITCH	REF	ROLL	REF
Plus 1.0	6	**Plus 1.0**	F
Plus 1.5	7	**Plus 1.5**	G

Note: *1. This procedure can only be used if :*
- *The PITCH and ROLL data is taken from the ADIRS (Make sure that the FQIS Status page does not show "NO DATA FROM ADIRU 1" and "NO DATA FROM ADIRU 2").*
- *The PITCH data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*
- *The ROLL data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*

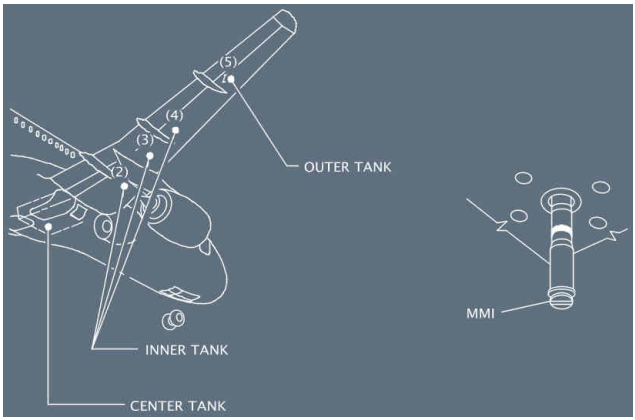
2. The FQIS input parameters are not automatically updated every 5.50 s

ACCESS PLATFORM.....IN POSITION

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

GENERAL

Indicators are installed as follows:
- Four in each wing tank: Three in the inner tank and one in the outer tank
- One in the center tank



TO DETERMINE AIRCRAFT ATTITUDE

Set ADIRS 1, 2, 3 to the NAV position.
On the LH or RH MCDU, press MCDU MENU pushbutton.
Select CFDS line key (LSK 4L).
Select SYSTEM REPORT/TEST line key (LSK 5L).
Select the line key adjacent to the FUEL indication.
On the MCDU control panel, push the NEXT PAGE key to display the FUEL Main Menu second page.
Select the line key adjacent to the INPUT PARAMETERS VALUES indication.
Use the Table given on the next page to determine the equivalent number and letter from PITCH and ROLL data.
Select RETURN line key (LSK 6L) until CFDS main menu appears.
Press MCDU MENU pushbutton.

PITCH	REF	ROLL	REF
Minus 1.5	1	**Minus 1.5**	A
Minus 1.0	2	**Minus 1.0**	B
Minus 0.5	3	**Minus 0.5**	C
0.0	4	**0.0**	D
Plus 0.5	5	**Plus 0.5**	E
Plus 1.0	6	**Plus 1.0**	F
Plus 1.5	7	**Plus 1.5**	G

Note: *1. This procedure can only be used if:*

- *The PITCH and ROLL data is taken from the ADIRS (identified by an "A" after the PITCH and ROLL title).*
- *The PITCH data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*
- *The ROLL data displayed for the LEFT, CTR, and RIGHT is no more or less than 0.1 of each other.*

2. The FQIS input parameters are not automatically updated. Use the NEXT PAGE control on the MCDU to cycle the pages to update the screen.

ACCESS PLATFORM.....IN POSITION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

TO DETERMINE FUEL QUANTITY IN THE OUTER TANK

MMI number 5.....UNLOCK and WITHDRAW

The crewmember must withdraw the MMI slowly until he feels the magnetic attraction between the rod and float magnets.

Do not use force when withdrawing the MMI as this will disengage the float magnet from the rod magnet and bring the rod down onto the mechanical stop.

ROD GRADUATION (which aligns with bottom wing surface).....READ

MMI..... IN PLACE and LOCKED

Use the table for the applicable aircraft wing side, aircraft attitude (grid square letter and number), and the MMI stick number 5, to find the volume of fuel in the outer tank (See below).

Multiply the result by the specific gravity to find the fuel weight.

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

MMI (from number 7 to number 1).....UNLOCK and WITHDRAW

The crewmember must slowly withdraw the MMI, until magnetic attraction is felt between the rod and float magnets.

Do not use force when withdrawing the MMI, as this will disengage the float magnet from the rod magnet, and bring the rod down on to the mechanical stop.

ROD GRADUATION (which aligns with bottom wing surface).....READ

MMIs shall be withdrawn from number 7 to number 1 until one MMI measures fuel.

MMI..... IN PLACE and LOCKED

Enter the table for the applicable aircraft wing side, aircraft attitude (grid square letter and number), and the applicable MMI stick number, to find the volume of fuel in the wing tank (See below).

Multiply the result by the specific gravity to find the fuel weight.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

MMI (from number 4 to number 2).....UNLOCK and WITHDRAW

The crewmember must slowly withdraw the MMI, until magnetic attraction is felt between the rod and float magnets.

Do not use force when withdrawing the MMI, as this will disengage the float magnet from the rod magnet, and bring the rod down on to the mechanical stop.

ROD GRADUATION (which aligns with bottom wing surface).....READ

MMIs shall be withdrawn from number 4 to number 2 until one MMI measures fuel.

MMI..... IN PLACE and LOCKED

Enter the table for the applicable aircraft wing side, aircraft attitude (grid square letter and number), and the applicable MMI stick number, to find the volume of fuel in the wing tank (See below).

Multiply the result by the specific gravity to find the fuel weight.

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN

TO DETERMINE FUEL QUANTITY IN THE INNER TANK

MMI (from number 4 to number 1).....UNLOCK and WITHDRAW

The crewmember must withdraw the MMI slowly until he feels the magnetic attraction between the rod and float magnets.

Do not use force when withdrawing the MMI as this will disengage the float magnet from the rod magnet and bring the rod down onto the mechanical stop.

ROD GRADUATION (which aligns with bottom wing surface).....READ
MMI..... IN PLACE and LOCKED

MMIs shall be withdrawn from number 4 to number 1 until one MMI measures fuel.

Use the table for the applicable aircraft wing side, aircraft attitude (grid square letter and number), and the applicable MMI stick number to find the volume of fuel in the inner tank (Refer to FCOM - PER.LOD.FUL FUEL. C.USE OF MANUAL MAGNETIC INDICATORS (MMI) - WING TANKS).
Multiply the result by the specific gravity to find the fuel weight.

Applicable to: B-HSO, B-HSP, B-HSQ, B-HSR

* GRID SQUARE LETTER

** GRID SQUARE NUMBER

GENERAL

Applicable to: ALL

This chart allows the determination of Aircraft CG location (MAC) function of dry operating weight, pantry adjustment, cargo loads, passengers and fuel on board.
The operational limits shown on the load and trim sheet are more restrictive than the certified limits because error margins have been taken into account.

The load and trim sheet needs to be updated when :
- a modification which changes the aircraft certified limits is included or
- a modification (cabin layout, cargo arrangement ...) which influences the operational limits is made.

It is the airline responsibility to define a load and trim sheet and to keep it up to date. *Refer to PER-LOD-WBA-LTS DESCRIPTION* is a description of the Load and Trim Sheet utilization (*Refer to PER-LOD-WBA-LTS LOAD AND TRIM SHEET*), for a typical passenger arrangement.
Refer to customized load and trim sheet for preparing a revenue flight.

DATA

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Dry Operating Weight = 42 500 kg and CG = 27 % (H-arm = 18.93 m)
Deviation or adjustment = + 100 kg in zone F
Cargo = 5 500 kg with the following distribution:
cargo 1 = 2 000 kg; cargo 3 = 1 500 kg; cargo 4 = 1 500 kg; cargo 5 = 500 kg
Passengers = 145 PAX with the following distribution:
cabin OA = 50; cabin OB = 55; cabin OC = 40
Ramp Fuel = 13 200 kg; Taxi Fuel = 200 kg; Fuel Density = 0.785 kg/l

DATA

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Dry Operating Weight = 49 000 kg and CG = 22 % (H-arm = 23 m)
Deviation or adjustment = + 100 kg in zone F
Cargo = 8 500 kg with the following distribution:
cargo 1 = 1 000 kg; cargo 2 = 1 000 kg; cargo 3 = 3 000 kg; cargo 4 = 3 000 kg; cargo 5 = 500 kg
Passengers = 180 PAX with the following distribution:
cabin OA = 50; cabin OB = 70; cabin OC = 60
Ramp Fuel = 17 200 kg
Taxi Fuel = 200 kg
Fuel Density = 0.785 kg/l

DESCRIPTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

a. Enter Master data in (1).
b. Compute Dry Operating Weight Index using the formula indicated in (2) and report in (3).
c. Dry Operating Index = 53.4.
d. Enter weight deviation or adjustment in (4) and read corresponding index variation in (5): +1.43.
e. Calculate corrected index and report in (6): 54.83.
f. Enter master data in table (7) and determine Zero Fuel Weight: 60 280 kg and Takeoff Weight: 73 280 kg.
g. Enter cargo weight and passenger number per compartment in (8).
h. Enter index scale (9) with corrected index and proceed through cargo and passenger scales (10).
i. From the final point draw a vertical line which intersects (12) the zero fuel weight horizontal line (11).
j. Check if the intersection point is within the Zero Fuel Weight operational limits, if not rearrange cargo loading.
k. Read in table (13) the fuel index correction corresponding to Ramp Fuel Weight (13 200 kg) and Fuel Density (0.785 kg/l).
   This example will be continued assuming the FUEL INDEX = –2 was found. Carry in fuel scale (14).
l. From this point draw a vertical line which intersects (16) the takeoff weight horizontal line (15).
m. Check if the intersection point is within the Takeoff Weight operational limits.
n. Read zero fuel weight and CG position: 32.7 % and fill in table (17).
o. Read takeoff CG position: 30.5 % and fill in table (18).

CAUTION	If there is no customized trim sheet for your airline in this section, do not use the information enclosed herein for day to day operation as margins and load CG vary with cabin and cargo layout.

Note: *When referring to CG lower than 27 %, an operational margin is taken into account. It is the reason why performance at forward CG (lower than 25 %) must be used for operational CG lower than 27 %.*

DESCRIPTION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

a. Enter Master data in (1).
b. Compute Dry Operating Weight Index using the formula indicated in (2) and report in (3).
c. Dry Operating Index = 43.96.
d. Enter weight deviation or adjustment in (4) and read corresponding index variation in (5): +1.70.
e. Calculate corrected index and report in (6): 45.66.
f. Enter master data in table (7) and determine Zero Fuel Weight: 72 720 kg and Takeoff Weight: 89 720 kg.
g. Enter cargo weight and passenger number per compartment in (8).
h. Enter index scale (9) with corrected index and proceed through cargo and passenger scales (10).
i. From the final point draw a vertical line which intersects (12) the zero fuel weight horizontal line (11).
j. Check if the intersection point is within the Zero Fuel Weight operational limits, if not rearrange cargo loading.
k. Read in table (13) the fuel index correction corresponding to Ramp Fuel Weight (17 200 kg) and Fuel Density (0.785 kg/l).
   This example will be continued assuming the FUEL INDEX = –10 was found.
   Carry in fuel scale (14).
l. From this point draw a vertical line which intersects (16) the takeoff weight horizontal line (15).
m. Check if the intersection point is within the Takeoff Weight operational limits.
n. Read zero fuel weight and CG position: 32 % and fill in table (17).
o. Read takeoff CG position: 28 % and fill in table (18).

CAUTION	If there is no customized trim sheet for your airline in this section, do not use the information enclosed herein for day to day operation as margins and load CG vary with cabin and cargo layout.

FUEL INDEX TABLE

GENERAL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The fuel index table has been established assuming a fuel distribution in accordance with refuel distribution given in section *Refer to PER-LOD-FUL GENERAL INFORMATION - REFUELING* of this volume.

If after refueling the actual distribution deviates from the chart values, the actual and the trim sheet CG will show a discrepancy. The following tables allow to determine the fuel index taking into account the actual fuel quantity in each tank. To determine the actual takeoff CG enter the tables with the actual fuel quantities in each tank, read the fuel index for each tank and use their sum to enter the trim sheet. Check that the actual CG is inside the operational limits. If the CG is outside the limits transfer fuel to achieve a distribution in accordance with the chart or rearrange the load.

Note: *These tables are valid only when used with the following formula for the index:*
I = W x (H-arm – 18.85)/1 000 + K or I = [(CG –25) x W x 0.000042] + K
(Weight in kg, H-arm in m)

DATA: Fuel in left inner fuel tank = 4 500 kg
Fuel in right inner fuel tank = 4 500 kg
Fuel in left outer fuel tank = 200 kg
Fuel in right outer fuel tank = FULL
Fuel in center tank = 0 kg

		Weight		Index
Inner tank	**Left**	4 500	-	3
	Right	4 500	-	3
Outer tank	**Left**	200		0
	Right	691	+	2
Center tank		0		0
TOTAL		9 891	-	4

Enter the trim sheet with a fuel index of –4

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The fuel index table has been established assuming a fuel distribution in accordance with refuel distribution given in section *Refer to PER-LOD-FUL GENERAL INFORMATION - REFUELING* of this volume.

If after refueling the actual distribution deviates from the chart values, the actual and the trim sheet CG will show a discrepancy. The following tables allow to determine the fuel index taking into account the actual fuel quantity in each tank. To determine the actual takeoff CG enter the tables with the actual fuel quantities in each tank, read the fuel index for each tank and use their sum to enter the trim sheet. Check that the actual CG is inside the operational limits. If the CG is outside the limits transfer fuel to achieve a distribution in accordance with the chart or rearrange the load.

Note: *These tables are valid only when used with the following formula for the index:*

GENERAL

Applicable to: ALL

The ground distance/air distance conversion tables show the air distance for a given ground distance due to the influence of the wind.

The Tables are given for :
- M .78
- Long range speed.

M.78

Applicable to: ALL

Intentionally left blank

GENERAL

Applicable to: ALL

The ground distance/air distance conversion tables are used to calculate the air distance for a given ground distance due to the influence of the wind.

Tables are given for :

- LONG RANGE SPEED
- FIXED SPEEDS

LONG RANGE SPEED

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

GENERAL

Applicable to: ALL

The thrust rating charts have been established for:

- Maximum takeoff
- Maximum go around
- Flexible takeoff
- Maximum continuous
- Maximum climb
- Maximum cruise

Intentionally left blank

DEFINITION

Applicable to: ALL

It is the maximum thrust certified for takeoff and is normally limited to five minutes.
This time is extended to ten minutes for engine out contingency, as authorized by the approved AFM.

MAXIMUM TAKEOFF

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Intentionally left blank

DEFINITION

Applicable to: ALL

It is a reduced takeoff thrust as compared to the maximum permissible. The related EPR is calculated as a function of the flexible temperature entered in the FMGS MCDU. The flexible temperature is a function of the aircraft weight and environmental conditions.
It guarantees that the regular performance requirements are met.

Intentionally left blank

DEFINITION

Applicable to: ALL

It is the maximum thrust certified for continuous use. This rating should be used, at the pilot's discretion, only when required to ensure safe flight (engine failure).

DEFINITION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

It is the maximum thrust approved for normal cruise.
There is no thrust lever position corresponding to this thrust rating.
It is not displayed to the pilot, and the EPR limit which is displayed in cruise is the maximum climb EPR.
The FMGS uses the maximum cruise EPR to compute the aircraft maximum speed.
In manual thrust setting, in cruise, the pilot should limit EPR to the maximum cruise EPR that is equal to the displayed maximum climb EPR minus 0.07.

DEFINITION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

It is the maximum thrust approved for normal cruise.
There is no thrust lever position corresponding to this thrust rating.
It is not displayed to the pilot, and the EPR limit which is displayed in cruise is the maximum climb EPR.
The FMGS uses the maximum cruise EPR to compute the aircraft maximum speed.
In manual thrust setting, in cruise, the pilot should limit EPR to the maximum cruise EPR that is equal to the displayed maximum climb EPR minus 0.075.

Intentionally left blank

N1 MODE THRUST CONTROL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

In case of no EPR available, the thrust control automatically reverts to N1 mode (rated or unrated).
Refer to PRO-ABN-70 ENG 1(2) EPR MODE FAULT.
If the N1 rated mode is lost on both engines, refer to the power management tables given on the following pages.
The herebelow table gives the N1 to be set in cruise to maintain M 0.78.

	FLIGHT LEVEL					
WEIGHT (1000 KG)	**290**	**310**	**330**	**350**	**370**	**390**
56	78.1	78.1	78.2	78.4	79.1	80.5
58	78.3	78.4	78.5	78.7	79.5	81.1
60	78.5	78.6	78.8	79.1	79.9	81.6
62	78.7	78.9	79.1	79.4	80.4	82.4
64	78.9	79.1	79.4	79.8	80.9	83.2
66	79.2	79.4	79.7	80.2	81.5	84.1
68	79.4	79.7	80	80.6	82.1	85.2
70	79.7	80	80.4	81.1	82.9	
72	79.9	80.2	80.7	81.6	83.7	
74	80.2	80.6	81.1	82.2	84.6	
76	80.5	80.9	81.5	82.8	85.9	
78	80.7	81.3	82	83.5		
80	81.1	81.6	82.5	84.3		
82	81.3	81.9	83	85.5		N1 (%)

Drift Down ceilings and go around performance are affected as follows:
Drift down ceiling:

Actual Weight (1 000 kg)	**50**	**60**	**70**	**80**	**90**
Ceiling Penalty (ft)	4 000	4 000	4 900	6 000	5 400

Go around weight:

Normal go around Weight (1 000 kg)	**45**	**50**	**55**	**60**	**65**	**70**	**75**	**80**	**85**
Weight Penalty (1 000 kg)	5.9	6.5	7.2	7.8	8.5	9.1	9.8	10.4	11.1

N1 MODE THRUST CONTROL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

In case of no EPR available, the thrust control automatically reverts to N1 mode (rated or unrated).
Refer to PRO-ABN-70 ENG 1(2) EPR MODE FAULT.
If the N1 rated mode is lost on both engines, refer to the power management tables given on the following pages.
The herebelow table gives the N1 to be set in cruise to maintain M 0.78.

DEFINITION OF FLEXIBLE TAKEOFF

DEFINITION OF FLEXIBLE TAKEOFF

Applicable to: ALL

In many cases the aircraft takes off with a weight lower than the maximum permissible takeoff weight. When this happens, it can meet the required performance (runway, second segment, obstacle,...) with a decreased thrust that is adapted to the weight : this is called FLEXIBLE TAKEOFF and the thrust is called FLEXIBLE TAKEOFF THRUST.
The use of flexible takeoff thrust saves engine life.

Intentionally left blank

USE OF FLEXIBLE TAKEOFF

USE OF FLEXIBLE TAKEOFF

Applicable to: ALL

The pilot can use flexible takeoff when the actual takeoff weight is lower than the maximum permissible takeoff weight for the actual temperature. The maximum permissible takeoff weight decreases when temperature increases, so it is possible to assume a temperature at which the actual takeoff weight would be the limiting one. This temperature is called FLEXIBLE TEMPERATURE or assumed temperature and is entered in the FADEC via the MCDU PERF TO page in order to get the adapted thrust.

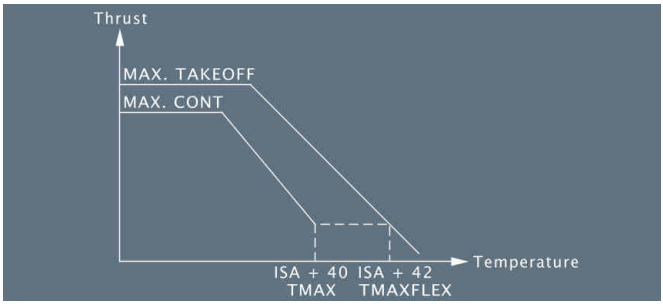
Intentionally left blank

REQUIREMENTS

REQUIREMENTS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

- Thrust must not be reduced by more than 25 % of the full rated takeoff thrust.
- The flexible takeoff EPR cannot be lower than the Max climb EPR at the same flight conditions. The FADEC takes the above two constraints into account to determine flexible EPR.
- The flexible takeoff thrust cannot be lower than the Max Continuous thrust used for the final takeoff flight path computation (at ISA +40).
  This constraint limits the maximum flexible temperature at ISA + 42 (57 °C at sea level).
- The flexible temperature cannot be lower than the flat rating temperature, TREF (See Note), or the actual temperature (OAT).



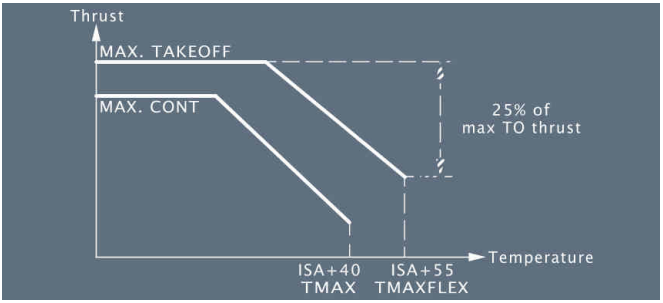
Note: *Tref being a function of the speed and the pressure-altitude, read it on the takeoff chart.*

- Flexible takeoff is not permitted on contaminated runways.
- The operator should check the maximum thrust (TOGA) at regular intervals in order to detect any engine deterioration, or maintain an adequate engine performance monitoring program to follow up the engine parameters.

REQUIREMENTS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

- Thrust must not be reduced by more than 25 % of the full rated takeoff thrust.
- The flexible takeoff EPR cannot be lower than the Max climb EPR at the same flight conditions. The FADEC takes the above two constraints into account to determine flexible EPR. The above two constraints also limit the maximum flexible temperature at ISA + 55 (70 °C at sea level).
- The flexible takeoff thrust cannot be lower than the Max Continuous thrust used for the final takeoff flight path computation (at ISA +40).
- The flexible temperature cannot be lower than the flat rating temperature, TREF (See Note), or the actual temperature (OAT).



Note: TREF being a function of pressure altitude, read it on the takeoff chart.

- Flexible takeoff is not permitted on contaminated runways.
- The operator should check the maximum thrust (TOGA) at regular intervals in order to detect any engine deterioration, or maintain an adequate engine performance monitoring program to follow up the engine parameters.

RECOMMENDATION

GENERAL

Applicable to: ALL

- In order to extend engine life and save maintenance costs, it is recommended to use flexible thrust reduction.
- However, to improve the takeoff performance, the thrust can be increased by selecting a lower flexible temperature.

Using the same takeoff chart, for a given weight it is possible to :
- Select a temperature lower than the maximum determined one and keep the speeds defined at maximum temperature or,
- Move towards the left side (tailwind) of the takeoff chart while remaining within the same configuration and looking for the same actual takeoff weight at lower temperature.
  This produces a lower flexible temperature and, in general, lower takeoff speeds (V1/VR/V2).

Using one of the two above possibilities, check that the selected temperature is greater than the actual temperature (OAT) and greater than the flat rating temperature (TREF).

TAKEOFF PROCEDURE

Applicable to: ALL

Depending on environmental takeoff conditions, the following procedure is recommended.

CONDITIONS	PROCEDURE	REASON
Dry or wet well paved runway	- Use the flap setting giving the highest flexible temperature. - When flexible temperature difference between two flap settings is low, use the highest flap setting.	Extend engine life and save maintenance costs.
High altitude takeoff	Use CONF2/CONF3	Improve comfort
Badly paved runway or Accelerate stop distance limited runway	Use CONF2/CONF3 or Move towards left side of the takeoff chart	Improve comfort Improve stopping distance
Windshear expected along takeoff path	Use maximum thrust	Maintain acceleration capability
Contaminated runway	Use maximum thrust (flex forbidden)	Improve stopping distance Decrease time on runway. Required by regulations.

Intentionally left blank

TAKEOFF CHARTS

Applicable to: ALL

Takeoff charts are required to provide performance at takeoff. It is possible to present the charts in two different ways, one of which is selected by the airline. The different presentations are :

- temperature entry (temperature provided in the left column)
- weight entry (weight provided in the left column).

Both presentations are described here after. Sections PER-TOF-TOC-10, 12 and 14 are relative to temperature entry while PER-TOF-TOC-16, 18 and 20 are relative to weight entry.

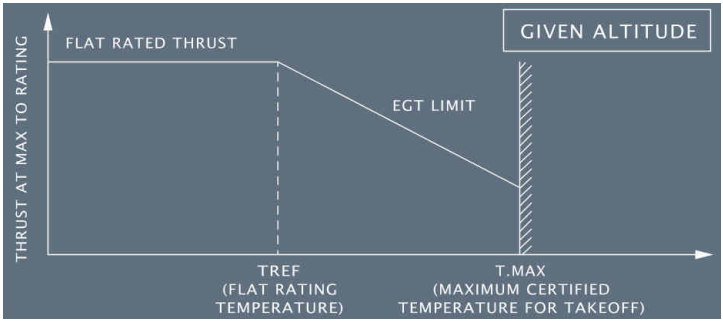
Intentionally left blank

TAKEOFF PERFORMANCE

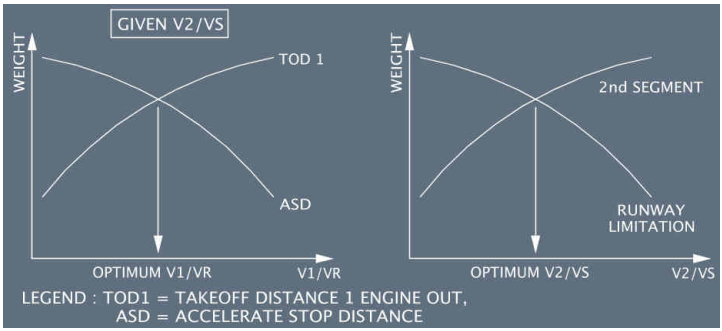
TAKEOFF PERFORMANCE

Applicable to: ALL

Takeoff optimization is calculated for a given runway and its obstacles and for given conditions of flap setting, temperature, wind and QNH. The calculation produces a maximum permissible takeoff weight (or a maximum takeoff temperature for an actual weight).
The takeoff thrust produced by the engine varies as follows :



The optimization process calculates the speeds which will produce the maximum takeoff weight. To do so, it takes into account the different takeoff limitations such as TOD, ASD, TOR, second segment..., as shown on the figure charts below.



On a typical runway, the performance of a twin engine aircraft, is generally limited by the one engine out operation at takeoff. The optimum V2/VS and optimum V1/VR are consequently unique.

Intentionally left blank

TAKEOFF CHART DESCRIPTION

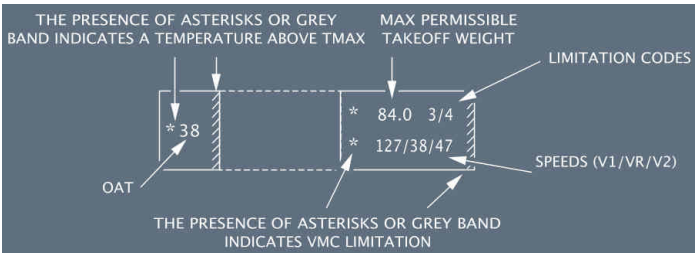
GENERAL

Applicable to: ALL

The takeoff chart (RTOW : Regulatory Takeoff Weight) is calculated for a specific aircraft version and for a particular runway specified at the top of the chart. The top of the chart also gives some information about the runway and lists the calculation assumptions.

The chart is given for 2 different configurations and 5 wind values per configuration. This allows the crew to select the configuration that gives either :
- the highest permissible takeoff weight, or, for a given weight,
- the highest flexible temperature.

If different configurations give equivalent performance, the crew should select the configuration associated with the lowest takeoff speeds.
For each temperature value (and for a given configuration and wind), the chart provides the following information :



The available limitation codes are :

- First segment	:	1
- Second segment	:	2
- Runway length	:	3
- Obstacles	:	4
- Tire speed	:	5
- Brake energy	:	6
- Maximum computation weight	:	7
- Final takeoff	:	8
- VMU	:	9

CORRECTIONS DUE TO DIFFERENT TAKEOFF CONDITIONS

Applicable to: ALL

Each takeoff chart is computed for a given set of conditions (air conditioning, QNH, anti ice...) specified at the top of the chart. If the actual takeoff conditions are different, the crew must apply corrections. Two types of corrections are available :

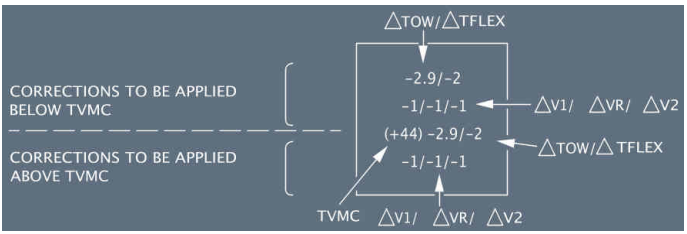
- Conservative corrections on *Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS*(to be used when not provided on the chart).
- Corrections (less restrictive) listed on the chart, to be applied as explained below.

Note: *If the RTOW chart is based on the CG being at 25 %, the crew can find the takeoff performance at a more forward CG by decreasing the takeoff weight by 1 000 kg (2 200 lb) and increasing V1, VR and V2 by 1 kt.*

DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART

Applicable to: ALL

The corrections are presented on 4 lines:



TVMC is a temperature value given per column. This is a fictitious value that indicates the temperature above which the speeds are close to a VMC limitation or are VMC limited.

Note: *The lower two lines may be shaded on certain chart formats.*

MINIMUM SPEEDS

Applicable to: ALL

Minimum V1/VR/V2 due to VMC are provided on the bottom right side of the takeoff chart.
They are only applicable in case of speed corrections.
These speeds are conservative. They may be slightly higher than V1/VR/V2 displayed on the takeoff chart.

FLEX TEMPERATURE INDICATOR

Applicable to: ALL

On the temperature entry chart, the temperature column may display asterisks or have a gray band to indicate temperature values above TMAX and which are flex temperature.

Intentionally left blank

ADDITIONAL INFORMATION

ONE ENGINE OUT CLIMB PROCEDURE

Applicable to: ALL

The performance given in the chart is consistent with the flight path specified for the aircraft with one engine out and takes into account significant obstacles.
When the procedure to be followed is not the standard instrument departure, the chart describes a specific procedure (EOSID).
When the specified procedure requires a turn, except if otherwise stated on the RTOW chart, the turn should be performed with a maximum bank of 15 ° until the aircraft reaches 1 500 ft or until green dot.
The acceleration height (or altitude) ensures that the net flight path clears the highest obstacle by at least 35 ft when accelerating in level flight to green dot speed after an engine failure, in the most adverse conditions.

TAKEOFF ON A WET RUNWAY

Applicable to: ALL

Takeoff charts computed for wet runway with a 15 ft screen height and/or use of reverse thrust may produce, in some conditions, a maximum takeoff weight (or flexible temperature) higher than that obtained for a dry runway. It is thus mandatory to compare both charts (dry and wet) and retain the lower of the two weights (or flexible temperature) and the associated speeds determined for a wet runway.

Note: *The crew need not compare the charts if the top of the wet runway chart specifies "DRY CHECK". (The comparison has already been inserted in the WET runway calculation).*

DETERMINATION OF MAXIMUM TAKEOFF WEIGHT AND SPEEDS

DIRECT CHART READING

Applicable to: ALL

The takeoff chart is computed for a given runway under a set of conditions, which are:
- OAT
- Wind
- Configuration
- QNH, air conditioning, anti ice...

Two configurations are produced on the chart. This enables the crew to select that giving the highest permissible takeoff weight. In case of equivalent performance, retain the configuration giving the lower takeoff speeds.
For a given configuration, enter the chart with the OAT and wind value to determine the maximum permissible weight. For an OAT or wind value not presented on the chart, interpolate between two consecutive temperature rows and/or two consecutive wind columns. Conservative OAT or wind values can also be considered. No extrapolation is allowed.

CORRECTIONS DUE TO DIFFERENT TAKEOFF CONDITIONS

Applicable to: ALL

Retain the maximum takeoff weight, associated configuration and speeds from above.
For conditions different from those of the chart, apply relevant corrections.

CONSERVATIVE CORRECTIONS FOR QNH AND BLEEDS

Specific: HDA
Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS

Corrections are given for QNH ≠1 013 hPa, air conditioning ON, anti ice ON.

1. For the given wind and temperature conditions, read the maximum takeoff weight (choose the configuration giving the highest weight).
2. Apply the published weight correction(s) to the maximum takeoff weight (for each correction) to determine the maximum permissible takeoff weight.
3. Read the speeds associated with the maximum permissible takeoff weight by entering the chart with the retained configuration and wind value.

EXAMPLE 1

DATA: OAT = 25 °C
Head Wind = 10 kt
Air conditioning ON
QNH = 1 013 hPa

Use the chart (*Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*)
Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F,
Maximum TO weight (1 000 kg) air conditioning OFF.....88.1
Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2,
Maximum TO weight (1 000 kg) air conditioning OFF.....88.1
Retain CONF 2 as takeoff configuration as the speeds are lower.
Maximum TO weight (1 000 kg) air conditioning OFF.....82.2
Air conditioning correction..... - 2.3
(Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS)
Maximum permissible TO weight (1 000 kg) air conditioning ON..... = 79.9
Determine takeoff speeds for 79.9 (1 000 kg) in the 10 kt head wind column (CONF 2)
V1 = 152 kt, VR = 153 kt, V2 = 158 kt

CONSERVATIVE CORRECTIONS FOR QNH AND BLEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS

Corrections are given for QNH ≠1 013 hPa, air conditioning ON, anti ice ON.

1. For the given wind and temperature conditions, read the maximum takeoff weight (choose the configuration giving the highest weight).
2. Apply the published weight correction(s) to the maximum takeoff weight (for each correction) to determine the maximum permissible takeoff weight.
3. Read the speeds associated with the maximum permissible takeoff weight by entering the chart with the retained configuration and wind value.

EXAMPLE 1

DATA: OAT = 25 °C
Head Wind = 10 kt
Air conditioning ON
QNH = 1 013 hPa

Use the chart (*Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*)
Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F,
Maximum TO weight (1 000 kg) air conditioning OFF.....82.1
Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2,
Maximum TO weight (1 000 kg) air conditioning OFF.....82.1
Retain CONF 2 as takeoff configuration as the speeds are lower.
Maximum TO weight (1 000 kg) air conditioning OFF.....82.2
Air conditioning correction..... - 1.8
(Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS)
Maximum permissible TO weight (1 000 kg) air conditioning ON..... = 80.4
Determine takeoff speeds for 80.4 (1 000 kg) in the 10 kt head wind column (CONF 2)
V1 = 152 kt, VR = 153 kt, V2 = 158 kt

CORRECTIONS FOR WET OR CONTAMINATED RUNWAYS

Applicable to: ALL

(*Refer to PER-TOF-CTA-10 GENERAL*)

CORRECTIONS PRODUCED ON THE RTOW CHART

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

For example: *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*
A description of this correction is given on *Refer to PER-TOF-TOC-10-20 DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART*. The list of corrections is not exhaustive, however the most commonly used corrections are wet runway, QNH, air conditioning and/or anti ice. A maximum of three corrections can be produced on one chart.

To apply the corrections, proceed as follows:

1. Enter the chart with given OAT and wind to determine the maximum takeoff weight before correction.
2. Apply the first correction:
   If OAT is less than or equal to TVMC (line 3), apply ΔW correction from line 1 and ΔV1/ΔVR/ΔV2 corrections from line 2.
   Else, (for OAT greater than TVMC), apply ΔW correction from line 3 and ΔV1/ΔVR/ΔV2 corrections from line 4.
3. To combine a second (and third, as applicable) correction:
   If OAT is less than or equal to TVMC (line 3), apply ΔW correction from line 1 and ΔV1/VR/ΔV2 corrections from line 2.
   Check that the resulting speeds are higher than the minimum speeds displayed on the RTOW chart and that V2 is higher than the VMU limited speed (*Refer to PER-TOF-TOD-25-20 MINIMUM V2 LIMITED BY VMU/VMCA (KT IAS)*).
   If OAT is higher than TVMC (line 3) or if the above speed check is not fulfilled, apply ΔW correction from line 3 and ΔV1/ΔVR/ΔV2 corrections from line 4. No speed check is required.

Note:
- *QNH correction is given for ±10 hPa . It is allowed to extrapolate linearly for greater QNH deviation.*
- *When using a takeoff chart with failure cases, it is not allowed to combine two failure cases.*
- *Corrections from the chart must be applied from top to bottom, i.e. in the RTOW on Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART, apply the wet correction first.*
- *If asterisk or dotted lines appear in the correction boxes, refer to more conservative corrections provided in the FCOM.*
- *No speed check is required for the first correction. However, if the first influence correction follows a conversative FCOM correction, a speed check is required.*

EXAMPLE 2

DATA : OAT = 25 °C
Head Wind = 10 kt
QNH = 1 028 hPa

WET runway

Use the chart : *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART.*

- Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F, max TO weight (1 000 kg).....88.1
- Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2, max TO weight (1 000 kg).....88.1
- Retain CONF 2 for takeoff (takeoff speeds are lower).
- Read associated speeds as V1 = 155 kt, VR = 158 kt, V2 = 158 kt
- Apply WET correction
  For OAT < TVMC (54 °C), ΔW =..... 0.0
  Intermediate weight (1 000 kg).....= 88.1
  Associated speeds,
  V1 = 155 kt - 0 = 155 kt
  VR = 158 kt - 0 = 158 kt
  V2 = 158 kt - 0 = 158 kt
  (No speed check required for first correction)
- Apply QNH correction
  For OAT < TVMC (54 °C), ΔW = 0.3 × 15/10 =.....+ 0.4
  Maximum permissible takeoff weight (1 000 kg)..... = 88.5
  Associated speeds,
  V1 = 155 kt + 1 ×15/10 = 156 kt
  VR = 158 kt + 1 ×15/10 = 160 kt
  V2 = 158 kt + 1 ×15/10 = 160 kt
- Check that the speeds are higher than minimum speeds from the chart and from VMU table.

	Takeoff Configuration : 2			
	TOW	**V1**	**VR**	**V2**
TOW (RTOW)	88.1	155	158	158
FCOM correction(s)				
Intermediate value	88.1	155	158	158
WET Correction	0.0	0	0	0
Intermediate value	88.1	155	158	158

CORRECTIONS PRODUCED ON THE RTOW CHART

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

For example: *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*
A description of this correction is given on *Refer to PER-TOF-TOC-10-20 DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART*. The list of corrections is not exhaustive, however the most commonly used corrections are wet runway, QNH, air conditioning and/or anti ice. A maximum of three corrections can be produced on one chart.

To apply the corrections, proceed as follows:

1. Enter the chart with given OAT and wind to determine the maximum takeoff weight before correction.
2. Apply the first correction:
   If OAT is less than or equal to TVMC (line 3), apply ΔW correction from line 1 and ΔV1/ΔVR/ΔV2 corrections from line 2.
   Else, (for OAT greater than TVMC), apply ΔW correction from line 3 and ΔV1/ΔVR/ΔV2 corrections from line 4.
3. To combine a second (and third, as applicable) correction:
   If OAT is less than or equal to TVMC (line 3), apply ΔW correction from line 1 and ΔV1/VR/ΔV2 corrections from line 2.
   Check that the resulting speeds are higher than the minimum speeds displayed on the RTOW chart and that V2 is higher than the VMU limited speed (*Refer to PER-TOF-TOD-25-20 MINIMUM V2 LIMITED BY VMU/VMCA (KT IAS)*).
   If OAT is higher than TVMC (line 3) or if the above speed check is not fulfilled, apply ΔW correction from line 3 and ΔV1/ΔVR/ΔV2 corrections from line 4. No speed check is required.

Note:
- *QNH correction is given for ±10 hPa . It is allowed to extrapolate linearly for greater QNH deviation.*
- *When using a takeoff chart with failure cases, it is not allowed to combine two failure cases.*
- *Corrections from the chart must be applied from top to bottom, i.e. in the RTOW on Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART, apply the wet correction first.*
- *If asterisk or dotted lines appear in the correction boxes, refer to more conservative corrections provided in the FCOM.*
- *No speed check is required for the first correction. However, if the first influence correction follows a conversative FCOM correction, a speed check is required.*

EXAMPLE 2

DATA : OAT = 25 °C
Head Wind = 10 kt
QNH = 1 028 hPa

WET runway

Use the chart : *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART.*

- Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F, max TO weight (1 000 kg).....82.1
- Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2, max TO weight (1 000 kg).....82.1
- Retain CONF 2 for takeoff (takeoff speeds are lower).
- Read associated speeds as V1 = 156 kt, VR = 157 kt, V2 = 162 kt
- Apply WET correction
  ΔW =..... -1.2
  Intermediate weight (1 000 kg).....= 80.9
  Associated speeds,
  V1 = 156 kt - 10 = 146 kt
  VR = 157 kt - 1 = 156 kt
  V2 = 162 kt - 1 = 161 kt
  (No speed check required for first correction)
- Apply QNH correction
  ΔW = 0.2 × 15/10 =.....+ 0.3
  Maximum permissible takeoff weight (1 000 kg)..... = 81.2
  Associated speeds,
  V1 = 146 kt + 1 ×15/10 = 147 kt
  VR = 156 kt + 1 ×15/10 = 158 kt
  V2 = 161 kt + 1 ×15/10 = 163 kt
- Check that the speeds are higher than minimum speeds from the chart and from VMU table.

	Takeoff Configuration : 2			
	TOW	**V1**	**VR**	**V2**
TOW (RTOW)	82.1	156	157	162

COMBINING CORRECTIONS FROM FCOM AND CHART

Specific: HDA
Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Proceed as follows:

1. Enter the chart with selected configuration, OAT and wind to read the maximum takeoff weight.
2. Apply corrections from FCOM to determine an intermediate weight. Interpolate associated speeds for intermediate weight in the same column (same wind and configuration).
3. Apply corrections from RTOW chart as explained above.

EXAMPLE 3

DATA : OAT = 25 °C
Head wind = 10 kt
Air conditioning ON
QNH = 1 028 hPa
WET runway

1. Use the chart (*Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*).
   Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F,
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2,
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Retain CONF 2 for takeoff configuration as the speed are lower.
2. First, apply the correction (*Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS*).
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Air conditioning correction..... - 2.3
   Intermediate weight..... = 79.8
   Interpolate takeoff speeds for 79.8 (1 000 kg) in the 10 kt head wind column,
   V1 = 152 kt , VR = 153 kt , V2 = 158 kt
3. Apply WET correction
   For OAT < TVMC (54 °C), ΔW =..... - 1.2
   Intermediate weight..... = 78.6
   Associated speeds,
   V1 = 152 kt - 10 = 142 kt
   VR = 153 kt - 1 = 152 kt
   V2 = 158 kt - 1 = 157 kt
   Check that the speeds are higher than minimum speeds from the chart and from VMU table
   Apply QNH correction
   For OAT < TVMC (54 °C), ΔW = 0.2 × 15/10 =..... + 0.3
   Max permissible takeoff weight..... = 78.9
   Associated speed,

V1 = 142 kt + 1 ×15/10 = 143 kt
VR = 152 kt + 1 ×15/10 = 154 kt
V2 = 157 kt + 1 ×15/10 = 159 kt

Check that the speeds are higher than minimum speeds from the chart and from VMU table. (It is reminded that if the speed checks are not fulfilled, takeoff is not possible).
Since the speed check is fulfilled :
Max permissible takeoff weight = 78.9 (1 000 kg)
V1 = 143 kt, VR = 154 kt, V2 = 159 kt.

	Takeoff Configuration : 2			
	TOW	**V1**	**VR**	**V2**
TOW (RTOW)	82.1			
FCOM correction(s)	- 2.3			
Intermediate value	79.8	152	153	158
WET Correction	- 1.2	-10	-1	-1
Intermediate value	78.6	142	152	157
QNH Correction	+ 0.3	+1	+2	+2
Final value	78.9	143	154	159

COMBINING CORRECTIONS FROM FCOM AND CHART

Specific: HDA
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Proceed as follows:

1. Enter the chart with selected configuration, OAT and wind to read the maximum takeoff weight.
2. Apply corrections from FCOM to determine an intermediate weight. Interpolate associated speeds for intermediate weight in the same column (same wind and configuration).
3. Apply corrections from RTOW chart as explained above.

EXAMPLE 3

DATA : OAT = 25 °C
Head wind = 10 kt
Air conditioning ON
QNH = 1 028 hPa
WET runway

1. Use the chart (*Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*).
   Enter the 10 kt head wind column and interpolate for 25 °C, CONF 1+F,
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Enter the 10 kt head wind column and interpolate for 25 °C, CONF 2,
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Retain CONF 2 for takeoff configuration as the speed are lower.
2. First, apply the correction (*Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS*).
   Max TO weight (1 000 kg) air conditioning OFF..... 82.1
   Air conditioning correction..... - 1.8
   Intermediate weight..... = 80.3
   Interpolate takeoff speeds for 80.3 (1 000 kg) in the 10 kt head wind column,
   V1 = 152 kt , VR = 153 kt , V2 = 158 kt
3. Apply WET correction
   For OAT < TVMC (54 °C), ΔW =..... - 1.2
   Intermediate weight..... = 79.1
   Associated speeds,
   V1 = 152 kt - 10 = 142 kt
   VR = 153 kt - 1 = 152 kt
   V2 = 158 kt - 1 = 157 kt
   Check that the speeds are higher than minimum speeds from the chart and from VMU table
   Apply QNH correction
   For OAT < TVMC (54 °C), ΔW = 0.2 × 15/10 =..... + 0.3
   Max permissible takeoff weight..... = 79.4
   Associated speed,

V1 = 142 kt + 1 ×15/10 = 143 kt
VR = 152 kt + 1 ×15/10 = 154 kt
V2 = 157 kt + 1 ×15/10 = 159 kt

Check that the speeds are higher than minimum speeds from the chart and from VMU table. (It is reminded that if the speed checks are not fulfilled, takeoff is not possible).
Since the speed check is fulfilled :
Max permissible takeoff weight = 79.4 (1 000 kg)
V1 = 143 kt, VR = 154 kt, V2 = 159 kt.

	Takeoff Configuration : 2			
	TOW	**V1**	**VR**	**V2**

WET Correction	- 1.2	-10	-1	-1
Intermediate value	79.1	142	152	157
QNH Correction	+ 0.3	+1	+2	+2
Final value	79.4	143	154	159

Intentionally left blank

EXTRAPOLATION

EXTRAPOLATION

Applicable to: ALL

For a takeoff weight lower than those displayed on the chart, associated speeds are calculated as follows :

1. For given configuration and wind, note the speeds associated with the takeoff weight in the row displaying the highest permissible temperature.
2. Apply speed corrections provided at the bottom of the RTOW chart to V1, VR and V2 limited to the minimum speeds.

Intentionally left blank

MAXIMUM STRUCTURAL TAKEOFF WEIGHT

MAXIMUM STRUCTURAL TAKEOFF WEIGHT

Applicable to: ALL

The maximum structural takeoff weight is a weight limitation depending on the aircraft. This limitation is provided in the Flight Manual and in *Refer to LIM-11 Weight Limitations*. Compare the maximum structural takeoff weight to the maximum permissible takeoff weight computed for given conditions and retain the lower of the two values.

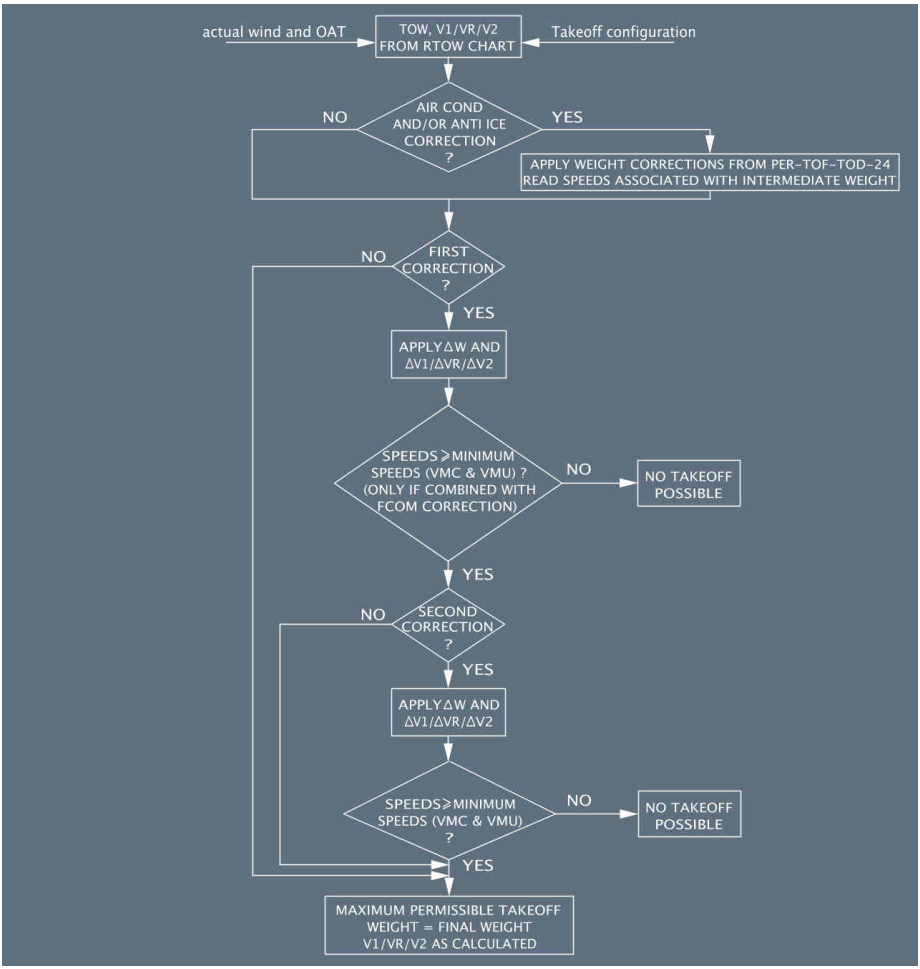
Intentionally left blank

SUMMARY

SUMMARY

Applicable to: ALL

The following flow diagram gives the different steps to follow.



Intentionally left blank

DETERMINATION OF FLEXIBLE TAKEOFF TEMPERATURE AND SPEEDS

GENERAL

Applicable to: ALL

Before determining the flexible temperature, calculate the maximum permissible takeoff weight (see previous section) and ensure that the actual takeoff weight is lower than the determined maximum takeoff weight.

- Enter the RTOW chart with the wind condition to interpolate for the actual takeoff weight. Read the flexible temperature in the temperature column corresponding to the actual weight.
- Repeat this process for the other configuration available. Select the configuration giving the highest flexible temperature.

CORRECTIONS DUE TO DIFFERENT TAKEOFF CONDITIONS

Applicable to: ALL

When the takeoff conditions are different from those provided on the chart, apply the associated corrections.

CONSERVATIVE CORRECTIONS FOR QNH AND BLEEDS

Applicable to: ALL

CONSERVATIVE CORRECTIONS FOR QNH AND BLEEDS

Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS

Corrections are given for QNH ≠1 013 hPa , air conditioning ON, anti ice ON.

1. For a given takeoff weight, wind condition and selected configuration, determine the flexible temperature. Retain the takeoff speeds associated with the actual weight.
2. Apply the published temperature correction. To combine two or more corrections, add the different corrections and apply to temperature value.
   (No speed corrections required).

EXAMPLE 4

DATA : Actual takeoff weight = 72 000 kg
Head wind = 10 kt
Air conditioning ON
QNH = 1 013 hPa

Use the chart *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*.
Determine the maximum permissible takeoff weight (*Refer to PER-TOF-TOC-12-10 CONSERVATIVE CORRECTIONS FOR QNH AND BLEEDS*). The actual weight being lower than the maximum one, flexible takeoff is possible.
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 1 + F,
Flexible temperature..... 52 °C
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 2,
Flexible temperature..... 53 °C
Retain CONF 2 for takeoff configuration.
Takeoff speeds are V1 = 149 kt, VR = 150 kt, V2 = 155 kt
Flexible temperature with air conditioning OFF..... 53 °C
Air conditioning correction..... -3 °C
Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS
Maximum flexible temperature..... = 50 °C

CORRECTIONS FOR WET RUNWAY

Applicable to: ALL

CORRECTIONS FOR WET RUNWAY

(*Refer to PER-TOF-CTA-10 GENERAL*)

CORRECTIONS PRODUCED ON THE RTOW CHART

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

A description of this correction is given on *Refer to PER-TOF-TOC-10-20 DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART*. The list of corrections is not exhaustive, however the most commonly used corrections are wet runway, QNH, air conditioning and/or anti-icing. A maximum of three corrections can be produced on one chart.

To apply the correction, proceed as follows:

1. Enter the chart with wind and selected configuration. Interpolate for actual takeoff weight. Read flexible temperature associated with this weight.
2. Apply the first correction:
   If the flexible temperature is less than or equal to TVMC (line 3), apply ΔTflex correction from line 1 and apply speed corrections (ΔV1/ΔVR/ΔV2) from line 2.
   Else, (flexible temperature greater than TVMC), apply ΔTflex from line 3 and ΔV1/ ΔVR/ ΔV2 corrections from line 4.
   Check V2 against VMU limitation (*Refer to PER-TOF-TOD-25-20 MINIMUM V2 LIMITED BY VMU/VMCA (KT IAS)*). If V2 is lower than V2 limited by VMU, flexible takeoff is not possible. Set TOGA thrust and retain the speeds associated with maximum permissible takeoff weight or the speeds read in the chart of the actual weight if they are all lower.
   No speed correction is required for QNH and bleeds influence (Not applicable to maximum takeoff weight determination).
3. To combine a second and/or a third correction, proceed as per point 2.
4. Check that the final flexible temperature is:
   - higher than OAT and TREF
   - limited to TMAXFLEX

   If the check is fulfilled, retain final flexible temperature as the one to be inserted in the MCDU.
   If the check is not fulfilled, (final flexible temperature lower than OAT or TREF), no flexible takeoff is possible.
   Use TOGA thrust and retain speeds that have been calculated for the maximum permissible takeoff weight. (*Refer to PER-TOF-TOC-14-20 FLEXIBLE TAKEOFF NOT POSSIBLE*)

Note:
- *QNH correction is given for ±10 hPa. It is allowed to extrapolate linearly for greater QNH deviation.*
- *Corrections from the chart must be applied from top to bottom, i.e. in the RTOW on Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART, apply the wet influence first.*

Note:
- *When the flexible temperature is higher than TVMC, it is allowed to limit the flexible temperature to TVMC and apply only corrections from lines 1 and 2.*
- *If asterisk or dotted lines appear in the correction boxes, refer to more conservative corrections provided in the FCOM.*

EXAMPLE 5

DATA : Actual takeoff weight = 65 000 kg
Head wind = 10 kt
QNH = 1 028 hPa
WET runway
Air conditioning OFF

Use the chart from *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*. Determine the maximum permissible takeoff weight (see example 2). The actual weight being lower than the maximum one, flexible takeoff is possible.

Enter the10 kt head wind column and interpolate for 65 000 kg, CONF 1 + F,
Flexible temperature..... 52 °C
Enter the10 kt head wind column and interpolate for 65 000 kg, CONF 2,
Flexible temperature..... 51 °C
Retain CONF 1 + F as the flexible temperature is higher.
Takeoff speeds are V1 = 146 kt, VR = 146 kt, V2 = 148 kt
Apply WET correction
For flexible temperature < TVMC (54 °C), ΔTflex =..... 0 °C
Intermediate flex temperature..... = 52 °C
Associated speeds,
V1 = 146 kt –4 = 142 kt
VR = 146 kt –1 = 145 kt
V2 = 148 kt –1 = 147 kt
Check V2 against VMU limitation on FCOM *Refer to PER-TOF-TOD-25-20 MINIMUM V2 LIMITED BY VMU/VMCA (KT IAS)*.
Apply QNH correction
For flex temperature < TVMC (54 °C), ΔTflex =..... 0 °C
Maximum flexible temperature..... = 52 °C
Check that OAT/TREF < flex temperature ≤ TMAXFLEX
No speed correction.
Takeoff speeds are V1 = 142 kt, VR = 145 kt, V2 = 147 kt

	Takeoff Configuration: 1 + F			
	Tflex	**V1**	**VR**	**V2**

CORRECTIONS PRODUCED ON THE RTOW CHART

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

A description of this correction is given on *Refer to PER-TOF-TOC-10-20 DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART*. The list of corrections is not exhaustive, however the most commonly used corrections are wet runway, QNH, air conditioning and/or anti-icing. A maximum of three corrections can be produced on one chart.

To apply the correction, proceed as follows:

1. Enter the chart with wind and selected configuration. Interpolate for actual takeoff weight. Read flexible temperature associated with this weight.
2. Apply the first correction:
   Apply ΔTflex correction and apply speed corrections (ΔV1/ ΔVR/ ΔV2).
   Check that the resulting speeds are higher than the minimum speeds displayed on the RTOW chart and that V2 is higher than the VMU limited speed *Refer to PER-TOF-TOD-25-20 MINIMUM V2 LIMITED BY VMU/VMCA (KT IAS)*. If the speed checks are not fulfilled, flexible takeoff is not possible. Set TOGA thrust and retain the speeds associated with maximum permissible takeoff weight or the speeds read in the chart of the actual weight if they are all lower.
   No speed correction is required for QNH and bleeds influence (Not applicable to maximum takeoff weight determination).
3. To combine a second and/or a third correction, proceed as per point 2.
4. Check that the final flexible temperature is:
   - higher than OAT and TREF
   - limited to TMAXFLEX

   If the check is fulfilled, retain final flexible temperature as the one to be inserted in the MCDU.
   If the check is not fulfilled, (final flexible temperature lower than OAT or TREF), no flexible takeoff is possible.
   Use TOGA thrust and retain speeds that have been calculated for the maximum permissible takeoff weight. (*Refer to PER-TOF-TOC-14-20 FLEXIBLE TAKEOFF NOT POSSIBLE*)

Note: - *QNH correction is given for ±10 hPa. It is allowed to extrapolate linearly for greater QNH deviation.*
- *Corrections from the chart must be applied from top to bottom, i.e. in the RTOW on Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART, apply the wet influence first.*

Note: - *If asterisk or dotted lines appear in the influence boxes, refer to more conservative corrections provided in the FCOM.*

EXAMPLE 5

DATA : Actual takeoff weight = 72 000 kg

Head wind = 10 kt
QNH = 1 028 hPa
WET runway
Air conditioning OFF

Use the chart from *Refer to PER-TOF-TOC-10-30 EXAMPLE OF TAKEOFF CHART*. Determine the maximum permissible takeoff weight (see example 2). The actual weight being lower than the maximum one, flexible takeoff is possible.
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 1 + F,
Flexible temperature..... 52 °C
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 2,
Flexible temperature..... 53 °C
Retain CONF 2 for takeoff configuration.
Takeoff speeds are V1 = 149 kt, VR = 150 kt, V2 = 155 kt
Apply WET correction
ΔTflex =..... -2 °C
Intermediate flex temperature..... = 51 °C
Associated speeds,
V1 = 149 kt –10 = 139 kt
VR = 150 kt –1 = 149 kt
V2 = 155 kt –1 = 154 kt
Check that the speeds are higher than minimum speeds from the chart and from VMU table.
Apply QNH correction
ΔTflex =..... 0 °C
Maximum flexible temperature..... = 51 °C
Check that OAT/TREF < flex temperature ≤ TMAXFLEX
No speed correction.
Takeoff speeds are V1 = 139 kt, VR = 149 kt, V2 = 154 kt

	Takeoff Configuration: 1 + F			
	Tflex	**V1**	**VR**	**V2**

COMBINING CORRECTIONS FROM FCOM AND CHART

Applicable to: ALL

1. Apply corrections from FCOM (*Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS*).
2. Apply corrections from the RTOW chart.
   Apply speed corrections except for QNH and bleed influences.

EXAMPLE 6

DATA: Actual takeoff weight = 72 000 kg
Head wind = 10 kt
Air conditioning ON
QNH = 1 028 hPa
WET runway

Use the chart (*Refer to PER-TOF-TOC-10-20 DESCRIPTION OF THE CORRECTIONS ON TAKEOFF CHART*). Determine the maximum permissible takeoff weight (*Refer to PER-TOF-TOC-12-10 COMBINING CORRECTIONS FROM FCOM AND CHART*: example 3).
The actual weight being lower than the maximum one, flexible takeoff is possible.
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 1 + F,
Flexible temperature..... 52 °C
Enter the 10 kt head wind column and interpolate for 72 000 kg, CONF 2,
Flexible temperature..... 53 °C
Retain CONF 2 for takeoff configuration.
Takeoff speeds are V1 = 149 kt, VR = 150 kt, V2 = 155 kt
First, apply the correction (*Refer to PER-TOF-TOD-24 EFFECT OF QNH AND BLEEDS*).
Flexible temperature with air conditioning OFF..... 53 °C
Air conditioning correction..... -3 °C
Intermediate flexible temperature.....= 50 °C
No speed correction.
Apply WET correction
ΔTflex = ... -2 °C
Intermediate flex temperature..... = 48 °C
Associated speeds,
V1 = 149 kt - 10 = 139 kt
VR = 150 kt - 1 = 149 kt
V2 = 155 kt - 1 = 154 kt
Check that the speeds are higher than minimum speeds from the chart and from VMU table.
Apply QNH correction
ΔTflex =..... 0 °C
Maximum flexible temperature..... = 48 °C
Check that OAT/TREF < flex temperature ≤ TMAXFLEX

No speed correction.
Takeoff speeds are V1 = 139 kt, VR = 149 kt, V2 = 154 kt

	Takeoff Configuration : 1 + F			
	Tflex	V1	VR	V2

Final value	48	139	149	154

Intentionally left blank

FLEXIBLE TAKEOFF NOT POSSIBLE

FLEXIBLE TAKEOFF NOT POSSIBLE

Applicable to: ALL

In some cases when the actual takeoff weight is lower than the maximum permissible one but no flexible takeoff possible (that is flexible temperature lower than TREF or OAT) :

- It is mandatory to use TOGA thrust
- You can retain the speeds that have been calculated for the maximum permissible takeoff weight; OR
- You can retain the speeds associated with the actual takeoff weight provided they are all lower than the speeds calculated for the maximum permissible takeoff weight.

Intentionally left blank

EXAMPLES

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

TAKEOFF CHART DATA

Airport geometric elevation = 450 ft
QNH = 1 013 hPa
Anti ice OFF
Air conditioning OFF

EXAMPLE 1-FULL THRUST TAKEOFF

Actual data : OAT = 5 °C
QNH = 1 040 hPa
Engine anti ice ON
Air conditioning OFF

Weight read in the takeoff chart: 85 000 kg
Determine the actual airport pressure altitude (1 hPa is equivalent to 28 ft according to the ISA model).
Pressure altitude = 450 – (1 040 – 1 013) × 28 = - 306 ft
Read in the above table the corrections for high QNH and engine anti ice ON.
QNH correction = 40 kg ×(450/28) + 0 kg ×(306/28) = + 640 kg
Engine anti ice correction: none
The maximum permissible takeoff weight is 85 000 + 640 = 85 640 kg

EXAMPLE 2-FLEXIBLE THRUST TAKEOFF

Actual data : OAT = 5 °C
QNH = 1 040 hPa
Anti ice OFF
Air conditioning ON
TOW = 75 000 kg

Flexible temperature read in the takeoff chart: TFLEX = 55 °C.
Read TREF on the takeoff chart or on the quick reference table.
Determine the actual airport pressure altitude (1 hPa is equivalent to 28 ft according to the ISA model).
Pressure altitude = 450 - (1 040 -1 013) × 28 = - 306 ft
Read in the above table the correction for QNH and air conditioning ON:
QNH correction = 1 °C/30 hPa ×(450/28) + 0 = 0 °C
Air conditioning ON correction: -3 °C
New flexible temperature = 55 + 0 -3 = 52 °C
Check that the flexible temperature is above TREF and actual OAT.

Check that the flexible temperature is less than the maximum flexible temperature and retain the lower of the two.

EXAMPLES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

TAKEOFF CHART DATA

Airport geometric elevation = 450 ft
QNH = 1 013 hPa
Anti ice OFF
Air conditioning OFF

EXAMPLE 1 - FULL THRUST TAKEOFF

Actual data : OAT = 5 °C
QNH = 1 040 hPa
Engine anti ice ON
Air conditioning OFF

Weight read in the takeoff chart: 73 000 kg
Read in the above table the corrections for high QNH and engine anti ice ON.
QNH correction: none
Engine anti ice correction: none
The maximum permissible takeoff weight is 73 000 + 0 - 0 = 73 000 kg

EXAMPLE 2 - FLEXIBLE THRUST TAKEOFF

Actual data : OAT = 5 °C
QNH = 1 040 hPa
Anti ice OFF
Air conditioning ON
TOW = 65 000 kg

Flexible temperature read on the takeoff chart: TFLEX = 55 °C.
Read TREF on the takeoff chart or on the quick reference table.
Read in the above table the correction for QNH and air conditioning ON:
QNH correction = none
Air conditioning ON correction: -3 °C
New flexible temperature = 55 - 3 = 52 °C
Check that the flexible temperature is above TREF and actual OAT.
Check that the flexible temperature is less than the maximum flexible temperature and retain the lower of the two.

SPEEDS LIMITED BY VMC

SPEEDS LIMITED BY VMC

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

All takeoff speeds have a minimum value limited by control. These minimum speeds are usually provided on each RTOW chart. If these speeds are not available, use the following conservative values. These speeds may be slightly higher than the minimum control speeds displayed on the RTOW chart.

MINIMUM V1												
CONF	PRESSURE ALTITUDE (FT)											
	-1 000	0	1 000	2 000	3 000	4 000	5 000	6 000	8 000	9 200	12 000	14 100

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

All takeoff speeds have a minimum value limited by control. These minimum speeds are usually provided on each RTOW chart. If these speeds are not available, use the following conservative values. These speeds may be slightly higher than the minimum control speeds displayed on the RTOW chart.

INTRODUCTION

INTRODUCTION

Applicable to: ALL

These tables enable the crew to quickly determine the takeoff performance at an airport for which no takeoff chart has been established. They are conservative.

Intentionally left blank

USE OF TABLES

USE OF TABLES

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

A first table gives the corrections to be applied to the runway length for wind and runway slope. Nine other tables give, for three different pressure altitudes (0, 1 000 and 2 000 ft) and three configurations, the maximum takeoff weight, limitation codes and associated speeds as a function of temperature and corrected runway length. TREF and TMAX are given on the top of each table. For pressure altitudes above 2 000 ft, use a specific RTOW chart.

Note: *1. Quick reference tables are established at V1 min with air conditioning OFF and anti ice OFF*

2. Do not use quick reference tables in case of tailwind.

USE OF TABLES

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

A first table gives the corrections to be applied to the runway length for wind and runway slope. Nine other tables give, for three different pressure altitudes (0, 1 000 and 2 000 ft) and three configurations, the maximum takeoff weight, limitation codes and associated speeds as a function of temperature and corrected runway length. TREF and TMAX are given on the top of each table. For pressure altitudes above 2 000 ft, use a specific RTOW chart.

Note: *1. Quick reference tables are established for the forward CG envelope (less than 25 %) at V1 min with air conditioning OFF and anti ice OFF*

2. Do not use quick reference tables in case of tailwind.

Intentionally left blank

HOW TO PROCEED

GENERAL

Applicable to: ALL

HOW TO PROCEED

1. Enter the first table with runway length, slope and wind data. Determine the corrected runway length by applying the corrections due to slope and wind.
2. Select the configuration as a function of this corrected runway length.
3. Enter the table(s) corresponding to the configuration and airport pressure altitude.

   As far as airport pressure altitude is concerned, two methods may be applied :
   - interpolate the takeoff performance by using the two tables enclosing the airport pressure altitude,
   - for a more conservative figure, use the table corresponding to the pressure altitude immediately above the airport pressure altitude.

4. Enter the appropriate column of the table(s) with the corrected runway length.

   Once again, two methods may be applied :
   - interpolate the takeoff performance between the two columns enclosing the corrected runway length,
   - for a more conservative figure, use the column corresponding to the shorter corrected runway length.

5. Determination of maximum takeoff weight.
   Enter the table(s) and column(s) as explained above with the actual OAT and read maximum takeoff weight, limitation codes, V1, VR and V2. If necessary interpolate weight and speeds.
6. Determination of flexible temperature.
   The determination of flexible temperature is possible only when there is no obstacle on the flight path. Enter the table(s) and column(s) with the actual takeoff weight and read the corresponding temperature as flexible temperature.
7. In case of obstacles, use the graphs (*Refer to PER-TOF-TOD-50 INTRODUCTION*) to determine the corresponding weight penalty.

LIMITATION CODES

Applicable to: ALL

- 1 : first segment
- 2 : second segment
- 3 : runway
- 5 : tire speed
- 6 : brake energy
- 7 : maximum computation weight
- 8 : final takeoff
- 9 : VMU

Note: 1. Limitation code 4 (obstacles) does not appear in quick reference tables.
2. VMC limitation appears with an asterisk (*) in the chart.

CORRECTIONS FOR WIND AND RUNWAY SLOPE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Runway length (m)		1 500	1 750	2 000	2 250	2 500	2 750	3 000	3 250	3 500
Effect of wind	per knot of head wind add (meters)	6	7.5	8	8.5	9.5	10	11	11.5	12.5
Effect of runway slope	per percent uphill slope subtract (meters)	100	150	200	280	375	475	600	725	820
	per percent downhill slope add (meters)	15	15	18	23	23	28	28	30	30

CORRECTIONS FOR WIND AND RUNWAY SLOPE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Runway length (m)		1 500	1 750	2 000	2 250	2 500	2 750	3 000	3 250	3 500
Effect of wind	per knot of head wind add (meters)	6.5	7	8	8.5	9.5	10	11	11.5	12.5
Effect of runway slope	per percent uphill slope subtract (meters)	160	215	270	325	380	435	490	545	600
	per percent downhill slope add (meters)	17	23	29	36	42	48	55	61	67

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Pressure altitude	:	1 400 ft
Temperature	:	31 °C
Runway length	:	2 750 m
Wind	:	10 kt head
Slope	:	1 % up
Takeoff configuration	:	1 + F

DETERMINATION OF CORRECTED RUNWAY LENGTH

(*Refer to PER-TOF-TOD-40-30 CORRECTIONS FOR WIND AND RUNWAY SLOPE*)

runway length ..... 2 750 m
correction for wind.....10 ×10 = + 100 m
correction for slope..... - 475 m
corrected runway length.....= 2 375 m

DETERMINATION OF A CONSERVATIVE MAXIMUM TAKEOFF WEIGHT:

(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 2000 FT*)

- Pressure altitude : 1 400 ft - Use the table for 2 000 ft.
- Enter the column corresponding to 2 250 m
- Read the maximum takeoff weight on the line corresponding to the temperature of 31 °C : 79 600 kg
  V1 = 139 kt, VR = 147 kt, V2 = 152 kt

DETERMINATION OF A PRECISE FLEXIBLE TEMPERATURE FOR THE ACTUAL TAKEOFF WEIGHT OF 74 000 KG:

(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 1000 FT*)
(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 2000 FT*)

- Interpolate the temperature corresponding to 74 000 kg for the runway length of 2 375 m at 1 000 ft and 2 000 ft pressure altitude.
  Results :
  1 000 ft : 54 °C, V1 = 139 kt, VR = 143 kt, V2 = 147 kt
  2 000 ft : 49 °C, V1 = 138 kt, VR = 143 kt, V2 = 147 kt
- Interpolate between these two values to get the flexible temperature
  1 400 ft : 52 °C, V1 = 139 kt, VR = 143 kt, V2 = 147 kt

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Pressure altitude	:	1 400 ft
Temperature	:	30 °C
Runway length	:	2 750 m
Wind	:	10 kt head
Slope	:	1 % up
Takeoff configuration	:	1 + F

DETERMINATION OF CORRECTED RUNWAY LENGTH

(*Refer to PER-TOF-TOD-40-30 CORRECTIONS FOR WIND AND RUNWAY SLOPE*)

runway length ..... 2 750 m
correction for wind.....10 ×10 = + 100 m
correction for slope..... - 435 m
corrected runway length.....= 2 415 m

DETERMINATION OF A CONSERVATIVE MAXIMUM TAKEOFF WEIGHT:

(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 2000 FT*)

- Pressure altitude : 1 400 ft - Use the table for 2 000 ft.
- Enter the column corresponding to 2 250 m
- Read the maximum takeoff weight on the line corresponding to the temperature of 30 °C :
  71 300 kg
  V1 = 140 kt, VR = 146 kt, V2 = 148 kt

DETERMINATION OF A PRECISE FLEXIBLE TEMPERATURE FOR THE ACTUAL TAKEOFF WEIGHT OF 64 000 KG:

(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 1000 FT*)
(*Refer to PER-TOF-TOD-40-40 CONFIGURATION 1+F / 2000 FT*)

- Interpolate the temperature corresponding to 64 000 kg for the runway length of 2 415 m at 1 000 ft and 2 000 ft pressure altitude.
  Results :
  1 000 ft : 66 °C, V1 = 138 kt, VR = 139 kt, V2 = 140 kt
  2 000 ft : 61 °C, V1 = 137 kt, VR = 139 kt, V2 = 140 kt
- Interpolate between these two values to get the flexible temperature
  1 400 ft : 64 °C, V1 = 137 kt, VR = 139 kt, V2 = 140 kt

Intentionally left blank

INTRODUCTION

Applicable to: ALL

The following graphs enable the crew to quickly determine the takeoff performance out of an airport by positioning obstacles.
They must be used with the corresponding quick reference table so as to determine weight decrement and required gradient.
The net takeoff flight path and the associated weight decrement are conservative.

HOW TO PROCEED

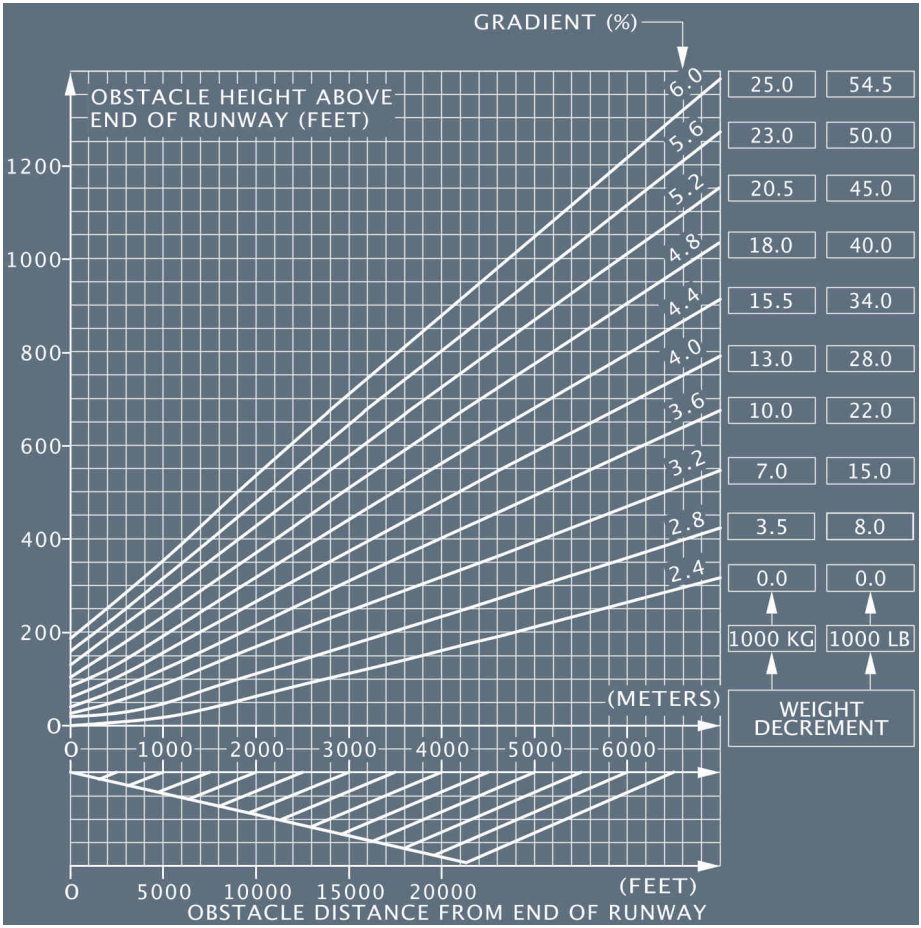
Applicable to: ALL

1. Position the obstacle by entering its distance from end of runway and its height above the end of runway (No 35 ft margin is required as this is already included).
   In case of an ascending runway, increase the obstacle height by an additional value as indicated below each graph.
2. Read the associated weight correction. Interpolate if necessary. The second segment gradient is given for information only.
3. Decrease the takeoff speeds by 1 kt per 1 000 kg (0.5 kt per 1 000 lb) weight decrement. Limit the final speeds to the minimum values (*Refer to PER-TOF-TOD-25-10 SPEEDS LIMITED BY VMC*).

   Note: *In case of tailwind, do not use the obstacle clearance graphs.*

CLOSE OBSTACLE CLEARANCE CONF 1 + F

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



Note: In case of ascending runway, increase obstacle height by 40 ft per percent runway slope.

Note: *In case of ascending runway, increase obstacle height by 50 ft per percent runway slope.*

GENERAL

Applicable to: ALL

This section presents the recommendations of Airbus for operations from wet runways or from runways which are covered with contaminants such as standing water, slush or snow.

CAUTION	Takeoff from an icy runway is not recommended.

Intentionally left blank

DEFINITIONS

Applicable to: ALL

DAMP	:	A runway is damp when the surface is not dry, but when the water on it does not give it a shiny appearance.
WET	:	A runway is considered as wet when the surface has a shiny appearance due to a thin layer of water. When this layer does not exceed 3 mm depth, there is no substantial risk of hydroplaning.
STANDING WATER	:	is caused by heavy rainfall and /or insufficient runway drainage with a depth of more than 3 mm.
SLUSH	:	is water saturated with snow which spatters when stepping firmly on it. It is encountered at temperatures around 5 °C and its density is approximately 0.85 kg/l (7.1 lb/US Gal).
WET SNOW	:	is a condition where, if compacted by hand, snow will stick together and tend to form a snowball. Its density is approximately 0.4 kg/l (3.35 lb/US Gal).
DRY SNOW	:	is a condition where snow can be blown if loose, or if compacted by hand, will fall apart again upon release. Its density is approximately 0.2 kg/l (1.7 lb/US Gal).
COMPACTED SNOW:		is a condition where snow has been compressed (a typical friction coefficient is 0.2).
ICY	:	is a condition where the friction coefficient is 0.05 or below.

The performance given in this chapter has been divided into two categories which are determined by the depth of the contaminant. For each of these categories an equivalent depth of contaminant has been defined for which the performance deterioration is the same.

1. WET RUNWAY and EQUIVALENT

Equivalent of a wet runway is a runway covered with or less than :

- 3 mm (0.12 in) slush
- 3 mm (0.12 in) water
- 4 mm (0.16 in) wet snow
- 15 mm (0.59 in) dry snow

2. CONTAMINATED RUNWAY

An equivalence between depth of slush and snow has been defined :

- 12.7 mm (1/2 in) wet snow is equivalent to 6.3 mm (1/4 in) slush
- 25.4 mm (1 in) wet snow is equivalent to 12.7 mm (1/2 in) slush
- 50.8 mm (2 in) dry snow is equivalent to 6.3 mm (1/4 in) slush

- 101.6 mm (4 in) dry snow is equivalent to 12.7 mm (1/2 in) slush

Note: *1. On a damp runway no performance degradation should be considered.*
2. It is not recommended to take off from a runway covered with more than 4 in of dry snow or 1 in of wet snow.

OPERATIONAL CONDITIONS

Applicable to: ALL

Performance penalties for takeoff as published in this section are computed with the following assumptions :

- The contaminant is in a layer of uniform depth and density over the entire length of the runway.
- Antiskid and spoilers are operative.
- The friction coefficient is based on studies and checked by actual tests.
- The screen height at the end of takeoff segment is 15 ft, not 35 ft.

In addition, for contaminated runways only :

- There is drag due to rolling resistance of the wheels.
- There is drag due to spray on the airframe and gears.
- Reverse thrust is used for the deceleration phase.
- Maximum thrust is used for takeoff.

Note: The net flight path clears obstacles by 15 ft instead of 35 ft.

Intentionally left blank

TAKEOFF PERFORMANCE

TAKEOFF PERFORMANCE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

CAUTION	The method is based on the use of the RTOW charts established at optimum V2/VS and optimum V1/VR. In addition, when applying corrections for a wet runway, the RTOW charts should also have been established with V1 min (minimum V1 of the V1 range). The method should not be used with takeoff charts computed for other conditions. All tables have been established for TOGA (and Flexible Takeoff for wet runways). Do not use them for Derated thrust.

Correct the determined maximum takeoff weight on dry runway to take into account QNH and bleed effects, then apply the corrections given on the following pages.

Note: *1. The results obtained with this method may be different from the influence given at the bottom of the RTOW chart.*
2. On contaminated runway, in some cases, no MTOW can be determined with this method (box dashed below a given weight). A specific RTOW chart must then be computed.

TAKEOFF PERFORMANCE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

CAUTION	The method is based on the use of the RTOW charts established at optimum V2/VS and optimum V1/VR. In addition, when applying corrections for a wet runway, the RTOW charts should also have been established with V1 min (minimum V1 of the V1 range). The method should not be used with takeoff charts computed for other conditions. All tables have been established for TOGA (and Flexible Takeoff for wet runways). Do not use them for Derated thrust.

Correct the determined maximum takeoff weight on dry runway to take into account QNH and bleed effects, then apply the corrections given on the following pages.

Note: *1. The results obtained with this method may be different from the influence given at the bottom of the RTOW chart.*
2. On contaminated runway, in some cases, no MTOW can be determined with this method (box dashed below a given weight). A specific RTOW chart must then be computed.
3. The published corrections are valid for charts calculated with forward CG and basic CG.

Intentionally left blank

TAKEOFF FROM A WET RUNWAY

HOW TO PROCEED

Applicable to: ALL

1. Determine the maximum takeoff weight or flexible temperature and associated speeds on dry runway.
2. Two sets of tables are given depending on the use of thrust reversers and the presence of clearway. Select the table to use as applicable to your case.
   The runway length in the table corresponds to the available takeoff run (TORA).
3. Apply the corrections shown in the table to the maximum takeoff weight or flexible temperature and associated speeds determined on dry runway.
4. Check that takeoff speeds are greater than the minimum values shown on the RTOW chart.

   If one or more speeds are lower than these minimum values, apply the following procedure :
   - Actual TOW = maximum TOW
     - If V1 is lower than the minimum V1 (V1 limited by VMCG), take this last value as V1 and further decrease weight by 3 000 kg (6 600 lb) per knot difference between them. Check that VR and V2 are higher than or equal to the minimum values.
     - If VR or/and V2 falls below the minimum values, takeoff is not possible.
   - Actual TOW lower than maximum TOW
     - If V1 corresponding to actual TOW is lower than the minimum V1 (V1 limited by VMCG) :
       - If maximum TOW has a V1 equal to or above minimum V1, retain minimum V1 as V1 and decrease the flexible temperature by 4 °C per knot difference between them.
       - In the rare case when the V1 corresponding to maximum TOW falls below the minimum V1, decrease maximum TOW by 3 000 kg (6 600 lb) per knot difference between them. Limit the actual TOW to the value found after this decrement. Take V1 equal to minimum V1 and decrease the flexible temperature by 4 °C per knot difference between this last value and the V1 corresponding to the actual TOW. Check that VR and V2 are higher than or equal to the minimum values.
     - If VR or V2 corresponding to actual TOW falls below the minimum values, and if VR and V2 corresponding to maximum TOW are above the minimum values, retain the minimum speed value for VR and V2.

5. Check that V2 is above the minimum V2 value due to VMU (*Refer to PER-TOF-TOD-25-10 SPEEDS LIMITED BY VMC*).
6. Check that the corrected flexible temperature is higher than OAT and Tref.

Note: - *Do not extrapolate below the shortest runway length provided in the table.*
- *If no minimum speed value is available, use the conservative values provided on Refer to PER-TOF-TOD-25-10 SPEEDS LIMITED BY VMC.*

GENERAL

Applicable to: ALL

Use this flight planning chapter when no precalculated flight plan is available.

It contains the following general graphs and tables :
- Maximum and optimum cruise altitudes for M .78 and long range speed
- Optimum altitude on short stage
- Ground mile to air mile conversion for M .78 and long range speed

The integrated range method includes the following tables :
- Integrated cruise tables for M .78 for flight levels from FL 290 to FL 390,
- Integrated cruise tables for long range speed for flight levels from FL 100 to FL 390,
- Climb, step climb and descent correction tables.

These tables allow the flight planning to be done segment by segment.
For calculation tables, *Refer to PER-FPL-FLP-CAT CALCULATION TABLE*. And for a comprehensive example to show how to use them, *Refer to PER-FPL-FLP-CAT EXAMPLE*.
For the quick determination method, *Refer to PER-FPL-FLP-QFP-40 FLIGHT PLANNING M.78* and *Refer to PER-FPL-FLP-QFP-50 FLIGHT PLANNING LRC*.

Intentionally left blank

MINIMUM RECOMMENDED FUEL REQUIREMENTS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The total fuel quantity required to fly a given sector is the sum of the following quantities:

TAXI FUEL

Quantity required for startup and taxi. Fuel calculation is based on a consumption of 11.5 kg/min or 25 lb/min
Average quantity (12 min) → 140 kg or 300 lb

TRIP FUEL

Fuel required from departure to destination includes the following quantities:
- Takeoff and climb at selected speed.
- Cruise at selected speed.
- Descent from cruising level to 1 500 ft above destination airport.
- Approach and landing. Fuel calculation is based on a consumption of 20 kg/min or 45 lb/min
  Average quantity (6 min IFR) →120 kg or 270 lb

RESERVE FUEL

This quantity includes :

"EN ROUTE" RESERVE FUEL (CONTINGENCY FUEL)

- According to national regulations and company policy (generally based on a percentage of trip fuel).

ALTERNATE FUEL

- Fuel required to fly from destination to alternate airport.

It includes go-around 100 kg or 220 lb, climb to cruising level, cruise at long range speed, descent and approach procedure.
80 kg or 180 lb for 4 min VFR

HOLDING FUEL

Calculation of holding fuel should take into account the altitude of the alternate and the landing weight at the alternate. To use holding charts *Refer to PER-HLD-GEN GENERAL*.
A conservative quantity corresponding to a 30 min holding at 1 500 ft above alternate airport elevation at "green dot" speed in the clean configuration is 1 200 kg or 2 700 lb

APU FUEL

During ground operations, APU fuel consumption is about 130 kg/h or 290 lb/h (Packs ON, 90 KVA load on APU GEN).

MINIMUM RECOMMENDED FUEL REQUIREMENTS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The total fuel quantity required to fly a given sector is the sum of the following quantities:

TAXI FUEL

Quantity required for startup and taxi. Fuel calculation is based on a consumption of 13.5 kg/min or 30 lb/min
Average quantity (12 min) → 160 kg or 360 lb

TRIP FUEL

Fuel required from departure to destination includes the following quantities:
- Takeoff and climb at selected speed.
- Cruise at selected speed.
- Descent from cruising level to 1 500 ft above destination airport.
- Approach and landing. Fuel calculation is based on a consumption of 23 kg/min or 50 lb/min
  Average quantity (6 min IFR) →140 kg or 310 lb

RESERVE FUEL

This quantity includes :

"EN ROUTE" RESERVE FUEL (CONTINGENCY FUEL)

- According to national regulations and company policy (generally based on a percentage of trip fuel).

ALTERNATE FUEL

Fuel required to fly from destination to alternate airport.
It includes go-around 120 kg or 270 lb, climb to cruising level, cruise at long range speed, descent and approach procedure.
100 kg or 220 lb for 4 min VFR

HOLDING FUEL

Calculation of holding fuel should take into account the altitude of the alternate and the landing weight at the alternate. To use holding charts *Refer to PER-HLD-GEN GENERAL*.
A conservative quantity corresponding to a 30 min holding at 1 500 ft above alternate airport elevation at "green dot" speed in the clean configuration is 1 450 kg or 3 200 lb

APU FUEL

During ground operations, APU fuel consumption is about 130 kg/h or 290 lb/h (Packs ON, 90 KVA load on APU GEN).

Intentionally left blank

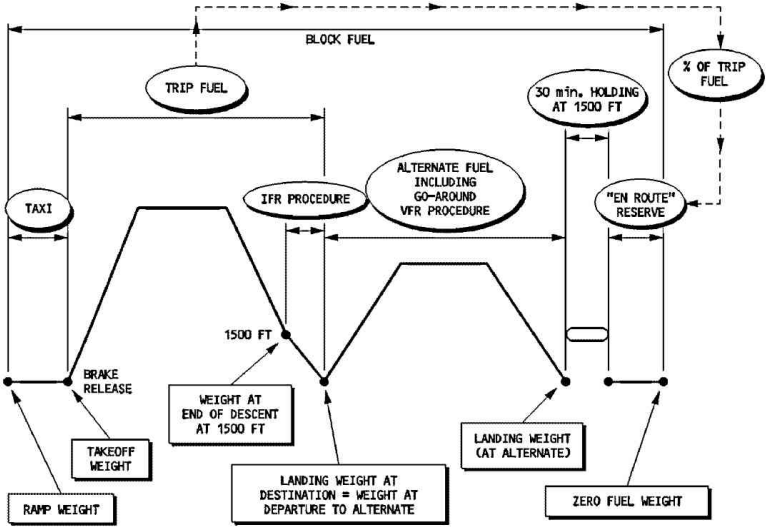
FLIGHT PLAN

Applicable to: ALL

When no precalculated flight plan is available, flight planning can be determined by using the tables given in this chapter.

Fuel policy will be the same as for precalculated flight plan.

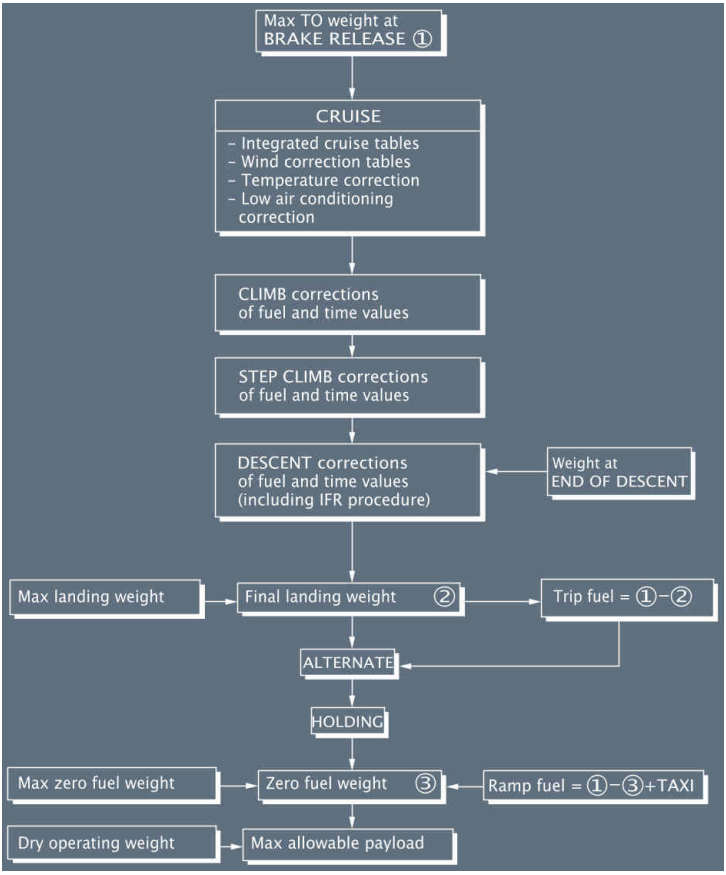
The graph on the following page defines the different terms used in this chapter.



Intentionally left blank

GENERAL

Applicable to: ALL



The following tables can be used for the flight planning.
The first table allows the planner to calculate fuel and time during cruise, with a possible step climb (*Refer to PER-FPL-FLP-CAT CALCULATION TABLE*).
The second table shows the fuel and time planning for the whole flight plan (*Refer to PER-FPL-FLP-CAT CALCULATION TABLE*).
At the end of the section an example shows how to use both tables for a given mission.

Note:
- *Differences in fuel consumption during step climb sections will be taken into account in the calculation table (Refer to PER-FPL-FLP-CAT CALCULATION TABLE).*
- *To find optimum aircraft weight to proceed to next flight level (4 000 ft step) (Refer to PER-CRZ-ALT-10 CRUISE LEVEL CHARTS GENERAL).*
- *Integrated cruise tables are established for ISA conditions only. Corrections due to differences from ISA temperature are included in the calculation table (Refer to PER-FPL-FLP-CAT CALCULATION TABLE).*
- *Overhead departure weight is assumed to be equal to weight at brake release.*
- *Overhead destination weight must be entered in the calculation table (Refer to PER-FPL-FLP-CAT CALCULATION TABLE).*

Line 10 : Check that landing weight at destination is lower than maximum landing weight.

Line 17 : Check that the zero fuel weight is lower than maximum zero fuel weight.

Line 22 : Check that the block fuel value is lower than maximum tank capacity.

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

DATA

- TO weight : 72 000 kg
- Ground distance to destination : 2 000 nm
- Wind : –50 kt (head wind)
- Selected initial FL : 350
- Mach number : M .78
- Temperature : ISA +10

DETERMINATION OF CRUISE FUEL AND TIME

A : Enter the chosen flight Mach number, flight level, ground distance to be covered and forecast windspeed in the calculation table (See CALCULATION TABLE).
Calculate the air distance (*Refer to PER-OPD-CON-AEO M.78*)
here : M .78, 50 kt head wind, 2 000 nm ground distance
→air distance : 2 248 nm

CRUISE TABLE FL350

B : Read from integrated cruise table (M .78, FL 350) the values for time and distance for a weight of 72 000 kg (*Refer to PER-FPL-FLP-ICR-20 INTEGRATED CRUISE - M.78 FL350*) :
→distance : 6 589 nm →time : 879 min

C : Read from *Refer to PER-CRZ-ALT-10 CRUISE LEVEL CHARTS GENERAL* the value for the optimum aircraft weight to proceed to FL 390 →62 000 kg

D : Enter integrated cruise table (M .78, FL 350) and read the values for a weight of 62 000 kg (begin of first step climb)
→distance : 4 703 nm →time : 628 min

E : Calculate the values for the first cruise segment :

Fuel	:	72 000 –62 000 = 10 000 kg
Distance	:	6 589 –4 703 = 1 886 nm
Time	:	879 –628 = 251 min
Remaining distance	:	2 248 –1 886 = 362 nm

CRUISE TABLE FL390

F : Read from integrated cruise table (M .78, FL 390) the values for time and distance for the weight of 62 000 kg (*Refer to PER-FPL-FLP-ICR-20 INTEGRATED CRUISE - M.78 FL390*)
→distance : 5 084 nm →time : 682 min

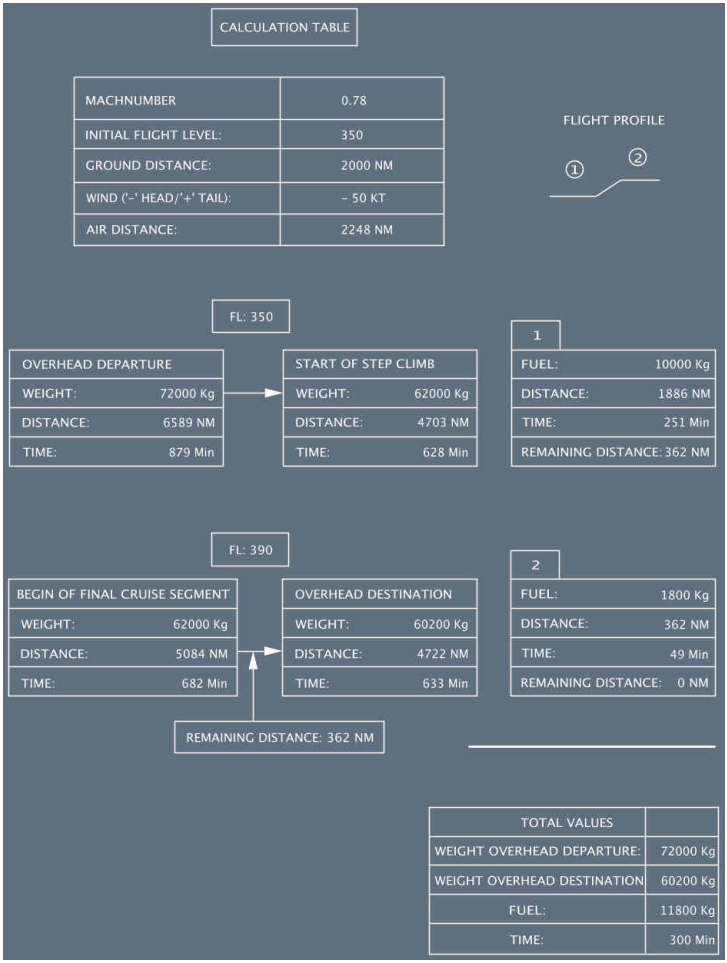
G : Subtract remaining distance : 5 084 –362 = 4 722 nm

H : Interpolate in integrated cruise table (M .78, FL 390) the weight and time values corresponding to the distance of 4 722 nm
→weight : 60 200 kg →time : 633 min

I : Calculate values for the second cruise segment :
Fuel : 62 000 –60 200 = 1 800 kg
Distance : 5 084–4 722 = 362 nm
Time : 682–633 = 49 min
Crosscheck that remaining air distance equals zero.

J : Fill in the final table with weight overhead departure (72 000 kg) and weight overhead destination (60 200 kg).

K : Calculate total values :
Fuel : 72 000 –60 200 = 11 800 kg
Time : 251 + 49 = 300 min = 5 h



DATA

- TO weight : 72 000 kg
- Ground distance to destination : 2 000 nm
- Wind : –50 kt
- Selected first flight level : FL 350
- M .78
- Temperature : ISA +10 along the whole flight profile

- Airport elevation : 1 500 ft
- Normal air conditioning

STEPS

1 : Fill in Max TO weight → 72 000 kg

2 : Enter the integrated cruise table corresponding to the chosen FL with TO weight at brake release point and calculate weight overhead destination. (See CALCULATION TABLE). Fill in → 60 200 kg

3 : Apply temperature correction for given air distance :
2 248 nm ×10 °C ×0.015/°C/NM = 337 kg (enter 400 kg into table)

4 : Correction for low air conditioning → here = 0

5 : Subtract climb correction for chosen FL (*Refer to PER-FPL-FLP-ICR-40 CLIMB CORRECTION*) → 1 050 kg

6 : Add TO altitude correction 0.5 × 72 × 1.5 = 54 kg (enter100 kg into table)

7 : Subtract value for step climb correction : 50 kg (enter 100 kg into table)

8 : Calculate corrected weight overhead destination → 58 700 kg

9 : Enter weight overhead destination and find descent correction (including 6 min IFR) (*Refer to PER-FPL-FLP-ICR-60 DESCENT CORRECTION*) → 300 kg

10 : Calculate landing weight at destination → 59 000 kg

11 : Subtract alternate fuel, e.g. : 100 nm at FL 100
(*Refer to PER-FPL-FLP-ALN-20 CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT*) → 984 kg
Landing weight at alternate → 59 000 - 984 = 58 016 kg
Correction due to deviation from reference landing weight at alternate (*Refer to PER-FPL-FLP-ALN-20 ALTERNATE PLANNING ISA*) → 6 × (58.0 - 55) = 18 kg
Corrected alternate fuel → 1 002 kg

12 : Calculate alternate landing weight → 58 000 kg

13 : Subtract holding fuel (*Refer to PER-HLD-GEN GENERAL*) → 1 098 kg

14 : Calculate weight at end of holding → 56 200 kg

15 : Calculate trip fuel → 13 000 kg

16 : Subtract “En Route” reserve (standard amount is 5 % of trip fuel) → 650 kg

17 : Calculate zero fuel weight → 56 200 kg

18-19: Subtract dry operating weight to obtain maximum allowable payload.

20-22: Calculate ramp fuel (*Refer to PER-FPL-GEN-MFR MINIMUM RECOMMENDED FUEL REQUIREMENTS* for taxi fuel).

23-26: Calculate flight time :

(See CALCULATION TABLE,
Refer to PER-FPL-FLP-ICR-40 CLIMB CORRECTION,
Refer to PER-FPL-FLP-ICR-60 DESCENT CORRECTION).

1	(1)	Max TO Weight at BRAKE RELEASE ▼	►		7	2	•	0

Line 22 : Check that the block fuel value is lower than maximum tank capacity.

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

DATA

- TO weight : 72 000 kg
- Ground distance to destination : 2 000 nm
- Wind : –50 kt (head wind)
- Selected initial FL : 350
- Mach number : M .78
- Temperature : ISA +10

DETERMINATION OF CRUISE FUEL AND TIME

A : Enter the chosen flight Mach number, flight level, ground distance to be covered and forecast windspeed in the calculation table (See CALCULATION TABLE).
Calculate the air distance (*Refer to PER-OPD-CON-AEO M.78*)
here : M .78, 50 kt head wind, 2 000 nm ground distance
→air distance : 2 248 nm

CRUISE TABLE FL350

B : Read from integrated cruise table (M .78, FL 350) the values for time and distance for a weight of 72 000 kg (*Refer to PER-FPL-FLP-ICR-20 INTEGRATED CRUISE - M.78 FL350*) :
→distance : 4 607 nm →time : 615 min

C : Read from *Refer to PER-CRZ-ALT-10 CRUISE LEVEL CHARTS GENERAL* the value for the optimum aircraft weight to proceed to FL 390 →68 000 kg

D : Enter integrated cruise table (M .78, FL 350) and read the values for a weight of 68 000 kg (begin of first step climb)
→distance : 3 900 nm →time : 521 min

E : Calculate the values for the first cruise segment :

Fuel	:	72 000 –68 000 = 4 000 kg
Distance	:	4 607 –3 900 = 707 nm
Time	:	615 –521 = 94 min
Remaining distance	:	2 248 –707 = 1 541 nm

CRUISE TABLE FL390

F : Read from integrated cruise table (M .78, FL 390) the values for time and distance for the weight of 68 000 kg (*Refer to PER-FPL-FLP-ICR-20 INTEGRATED CRUISE - M.78 FL390*)
→distance : 4 174 nm →time : 560 min

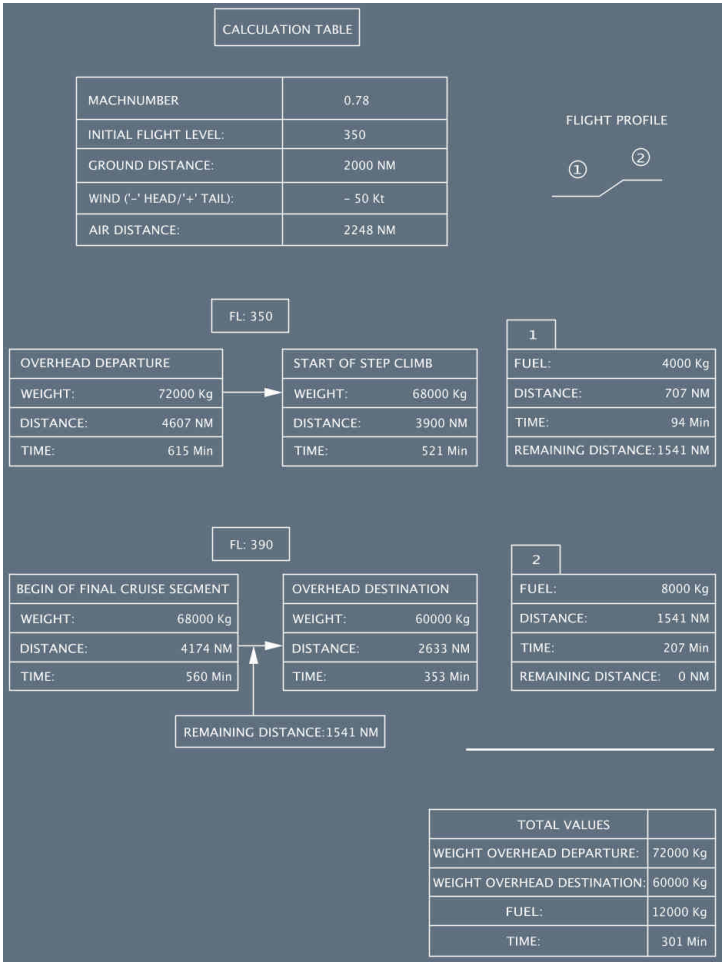
G : Subtract remaining distance : 4 174 –1 541 = 2 633 nm

H : Interpolate in integrated cruise table (M .78, FL 390) the weight and time values corresponding to the distance of 2 633 nm
→weight : 60 000 kg →time : 353 min

I : Calculate values for the second cruise segment :
Fuel : 68 000 –60 000 = 8 000 kg
Distance : 4 174 –2 633 = 1 541 nm
Time : 560 –353 = 207 min
Crosscheck that remaining air distance equals zero.

J : Fill in the final table with weight overhead departure (72 000 kg) and weight overhead destination (60 000 kg).

K : Calculate total values :
Fuel : 72 000 –60 000 = 12 000 kg
Time : 94 + 207 = 301 min = 5 h 01 min



DATA

- TO weight : 72 000 kg
- Ground distance to destination : 2 000 nm
- Wind : –50 kt
- Selected first flight level : FL 350
- M .78
- Temperature : ISA +10 along the whole flight profile

- Airport elevation : 1 500 ft
- Normal air conditioning

STEPS

1 : Fill in Max TO weight → 72 000 kg

2 : Enter the integrated cruise table corresponding to the chosen FL with TO weight at brake release point and calculate weight overhead destination. (See CALCULATION TABLE). Fill in → 60 000 kg

3 : Apply temperature correction for given air distance :
2 248 nm ×10 °C ×0.015/°C/NM = 337 kg (enter 400 kg into table)

4 : Correction for low air conditioning → here = 0

5 : Subtract climb correction for chosen FL (*Refer to PER-FPL-FLP-ICR-40 CLIMB CORRECTION*) → 1 000 kg

6 : Add TO altitude correction 0.5 x 72 x 1.5 = 54 kg (enter100 kg into table)

7 : Subtract value for step climb correction : 70 kg (enter 100 kg into table)

8 : Calculate corrected weight overhead destination → 58 600 kg

9 : Enter weight overhead destination and find descent correction (including 6 min IFR) (*Refer to PER-FPL-FLP-ICR-60 DESCENT CORRECTION*) → 200 kg

10 : Calculate landing weight at destination → 58 800 kg

11 : Subtract alternate fuel, e.g. : 100 nm at FL 100
(*Refer to PER-FPL-FLP-ALN-20 CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT*) → 1 098 kg
Landing weight at alternate → 58 800 - 1 098 = 57 702 kg
Correction due to deviation from reference landing weight at alternate (*Refer to PER-FPL-FLP-ALN-20 ALTERNATE PLANNING ISA*) → 6 x (57.7 - 60) = –13.8 kg
Corrected alternate fuel → 1 085 kg

12 : Calculate alternate landing weight → 57 700 kg

13 : Subtract holding fuel (*Refer to PER-HLD-GEN GENERAL*) → 1 200 kg

14 : Calculate weight at end of holding → 56 500 kg

15 : Calculate trip fuel → 13 200 kg

16 : Subtract “En Route” reserve (standard amount is 5 % of trip fuel) → 660 kg

17 : Calculate zero fuel weight → 55 800 kg

18-19: Subtract dry operating weight to obtain maximum allowable payload.

20-22: Calculate ramp fuel (*Refer to PER-FPL-GEN-MFR MINIMUM RECOMMENDED FUEL REQUIREMENTS* for taxi fuel).

23-26: Calculate flight time :

(See CALCULATION TABLE,
Refer to PER-FPL-FLP-ICR-40 CLIMB CORRECTION,
Refer to PER-FPL-FLP-ICR-60 DESCENT CORRECTION).

OPTIMUM AND MAXIMUM ALTITUDES

DEFINITIONS

Applicable to: ALL

- Optimum altitude : The altitude at which the airplane covers the maximum distance per kilogram (pound) of fuel (best specific range). It depends on the actual weight and deviation from ISA.
- Maximum altitude is defined as the lower of :
  - maximum altitude at maximum cruise thrust in level flight and
  - maximum altitude at maximum climb thrust with 300 ft/min vertical speed.

Note: Definition of the maximum altitude in the FMGC is different (Refer to DSC-22_20-40-30 Other Computations - Recommended Maximum Altitude (REC MAX)).

CRUISE LEVEL CHARTS - GENERAL

Applicable to: ALL

These charts have been established for a center of gravity at 33 % MAC.
Maximum and optimum altitudes are given for different temperatures at long range speed and M 78.

Note: The n = 1.3 g (1.4 g) curve indicates the buffet margin.

CRUISE LEVEL CHARTS - OPTIMUM WEIGHT FOR 4000 FEET STEP CLIMB

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

STEP CLIMB FROM/TO	WEIGHT (1 000 kg/1 000 lb)					
	≤ISA + 10		ISA + 15		ISA + 20	
	LR	M 0.78	LR	M 0.78	LR	M 0.78
310/350	75/165	75/165	74/163	73/160	70/154	69/152
330/370	68/149	69/152	68/149	67/147	64/141	64/141
350/390	61/134	62/136	61/134	61/134	58/127	57/125

CRUISE LEVEL CHARTS - OPTIMUM WEIGHT FOR 4000 FEET STEP CLIMB

According to the air distance (from brake release point to landing), the cruise flight level is limited by the distance required to perform climb and descent. The graph determines the optimum altitude.

It includes the following profiles:
- Takeoff
- Climb: 250 kt/300 kt/M .78
- Long range cruise (during at least 5 min)
- Descent: M .78/300 kt/250 kt
- Approach and landing

and it is established for:
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

GENERAL

GENERAL

Applicable to: ALL

Integrated cruise tables allow the planner to calculate the cruise fuel consumption and the cruise time required to cover a given air distance.
In the tables, the difference between two gross weights represents the fuel consumption. The difference between the corresponding distances and times respectively represents the cruise distance covered and the cruise time for this fuel consumption.
Integrated cruise tables are established for M .78 at fixed levels from FL 290 to FL 390 and for long range speed at fixed levels from FL 100 to FL 390.
Corrections are given on separate tables to allow for step climbs and to take into account the climb and the descent phases.

INTRODUCTION

INTRODUCTION

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following flight planning tables allow the planner to determine trip fuel consumption and trip time required to cover a given air distance.

These tables are established for:
- Takeoff
- Climb profile 250 kt/300 kt/M 0.78
- Cruise Mach number M 0.78/LR
- Descent profile M 0.78/300 kt/250 kt
- Approach and landing 120 kg - 6 min IFR
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

They are based upon a reference landing weight of 55 000 kg.

Note: *1. In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding FL.*
2. To obtain a flight plan at optimum cruise level, the highest flight level desired within the flight has to be selected in the table.
3. For each degree Celcius above ISA temperature apply fuel correction 0.015 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM).

INTRODUCTION

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The following flight planning tables allow the planner to determine trip fuel consumption and trip time required to cover a given air distance.

These tables are established for:
- Takeoff
- Climb profile 250 kt/300 kt/M 0.78
- Cruise Mach number M 0.78/LR
- Descent profile M 0.78/300 kt/250 kt
- Approach and landing 140 kg - 6 min IFR
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

They are based upon a reference landing weight of 60 000 kg and have been calculated using databases for CFM 56–5–B /P. If the engines fitted on the aircraft are not /P, the fuel consumption has to be increased by 3 % .

Note:
1. *In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding FL.*
2. *To obtain a flight plan at optimum cruise level, the highest flight level desired within the flight has to be selected in the table.*
3. *For each degree Celcius above ISA temperature apply fuel correction 0.015 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM).*

CORRECTION FOR DEVIATION FROM REFERENCE LANDING WEIGHT

CORRECTION FOR DEVIATION FROM REFERENCE LANDING WEIGHT

Applicable to: ALL

The fuel consumption must be corrected when the actual landing weight is different from the reference landing weight.

If it is lower (or greater) than the reference landing weight, subtract (or add) the value given in the correction part of the table per 1 000 kg below (or above) the reference landing weight.

Intentionally left blank

EXAMPLE

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following is an example of a complete flight plan based on the assumptions:
- Zero fuel weight: 60 000 kg = landing weight at alternate airport
- Cruise M .78 at FL 370
- Ground distance from departure to destination: 1 800 nm
- Average wind during flight: -40 kt (headwind)
- ISA conditions
- “En route” reserve: 5 %
- Ground distance from destination to alternate: 200 nm, no wind at FL 200

To calculate the flight plan, a reverse calculation is needed, i.e. start with the landing weight at alternate (the schematic *Refer to PER-FPL-GEN-FPL FLIGHT PLAN* gives an overview of the calculation to be performed).

1. Alternate fuel and time

   - *Refer to PER-FPL-FLP-ALN-20 ALTERNATE PLANNING ISA* ;
     Alternate time : 38 min
     Alternate fuel : 1 573 + 9 × (60 – 55) = 1 618 kg

2. Holding fuel and time

   - A 30 min holding is assumed at 1 500 ft. (*Refer to PER-HLD-HLD CONF 0 - GREEN DOT SPEED*), holding fuel = 1 090 kg

3. At destination, the landing weight = 60 000 + 1 618 + 1 090 = 62 708 kg
4. Evaluation of the air distance between departure and destination.

   - The “Ground distance/Air distance” conversion table (*Refer to PER-OPD-CON-AEO M.78*) shows that the corresponding air distance is: 1 975 nm.

5. Trip fuel and time

   - Enter air distance and flight level 370 (*Refer to PER-FPL-FLP-QFP-40 FLIGHT PLANNING M.78*), read the corresponding values of fuel consumption and time, for the reference landing weight and without deviation from ISA.
     Fuel : 10 205 kg
     Time = 4 h 37 min
   - Correction for landing weight
     Δfuel consumption : 146 × (62.7 – 55) = 1 124 kg
     Trip reserves (5 %) : 0.05 × (10 205 + 1 124) = 567 kg

6. Taxi fuel = 140 kg (*Refer to PER-FPL-GEN-MFR MINIMUM RECOMMENDED FUEL REQUIREMENTS*)
7. Total fuel on board (Block fuel) :
   10 205 + 1 124 + 567 + 1 090 + 1 618 + 140 = 14 744 kg

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The following is an example of a complete flight plan based on the assumptions:
- Zero fuel weight: 65 000 kg = landing weight at alternate airport
- Cruise M .78 at FL 370
- Ground distance from departure to destination: 1 800 nm
- Average wind during flight: -40 kt (headwind)
- ISA conditions
- “En route” reserve: 5 %
- Ground distance from destination to alternate: 200 nm, no wind at FL 200

To calculate the flight plan, a reverse calculation is needed, i.e. start with the landing weight at alternate (the schematic *Refer to PER-FPL-GEN-FPL FLIGHT PLAN* gives an overview of the calculation to be performed).

1. Alternate fuel and time

   - *Refer to PER-FPL-FLP-ALN-20 ALTERNATE PLANNING ISA* ;
     Alternate time : 38 min
     Alternate fuel : 1 725 + 9 × (65 – 60) = 1 770 kg

2. Holding fuel and time

   - A 30 min holding is assumed at 1 500 ft. (*Refer to PER-HLD-HLD CONF 0 - GREEN DOT SPEED*), holding fuel = 1 305 kg

3. At destination, the landing weight = 65 000 + 1 770 + 1 305 = 68 075 kg
4. Evaluation of the air distance between departure and destination.

   - The “Ground distance/Air distance” conversion table (*Refer to PER-OPD-CON-AEO M.78*) shows that the corresponding air distance is: 1 975 nm.

5. Trip fuel and time

   - Enter air distance and flight level 370 (*Refer to PER-FPL-FLP-QFP-40 FLIGHT PLANNING M.78*), read the corresponding values of fuel consumption and time, for the reference landing weight and without deviation from ISA.
     Fuel : 11 299 kg
     Time = 4 h 37 min
   - Correction for landing weight
     ∆fuel consumption : 149 × (68.075 – 60) = 1 204 kg
     Trip reserves (5 %) : 0.05 × (11 299 + 1 204) = 626 kg

6. Taxi fuel = 160 kg (*Refer to PER-FPL-GEN-MFR MINIMUM RECOMMENDED FUEL REQUIREMENTS*)
7. Total fuel on board (Block fuel) :
   11 299 + 1 204 + 626 + 1 305 + 1 770 + 160 = 16 364 kg

The alternate planning tables enable the flight crew to determine the fuel consumption and time required to cover a given air distance from go-around at destination airport to landing at alternate airport.

These tables are established for:
- Go-around: 100 kg or 220 lb
- Climb profile: 250 kt/300 kt/M .78
- Long range speed
- Descent profile: M .78/300 kt/250 kt
- Approach and landing at alternate airport: 80 kg or 180 lb (4 min)
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA temperature apply a fuel correction of
0.015 (kg/°C/NM) x ΔISA (°C) x Air distance (NM)
or 0.033 (lb/°C/NM) x ΔISA (°C) x Air distance (NM)

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The alternate planning tables enable the flight crew to determine the fuel consumption and time required to cover a given air distance from go-around at destination airport to landing at alternate airport.

These tables are established for:
- Go-around: 120 kg or 270 lb
- Climb profile: 250 kt/300 kt/M .78
- Long range speed
- Descent profile: M .78/300 kt/250 kt
- Approach and landing at alternate airport: 100 kg or 220 lb (4 min)
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA temperature apply a fuel correction of 0.015 (kg/°C/NM) x ΔISA (°C) x Air distance (NM) or 0.033 (lb/°C/NM) x ΔISA (°C) x Air distance (NM)

CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT

Applicable to: ALL

The alternate planning tables are based on a reference landing weight at alternate.
The fuel consumption must be corrected when the landing weight is different from the reference landing weight.
If it is lower (or greater) than the reference weight, subtract (or add) the value given in the correction part of the table per 1 000 kg or 1 000 lb below (or above) the reference weight.

GENERAL

Applicable to: ALL

This section provides guidance to operators on when an economical benefit to perform fuel tankering exists.
Fuel tankering is mainly considered for economic reasons, when the difference in fuel prices between departure airport and destination airport is significant.
Operators may also consider fuel tankering when the fuel supply is unreliable or the fuel type is unavailable.
The operator has to take into account additional costs due to the aircraft weight increase. These costs are not negligible and the operator should consider them against fuel tankering gains.

Main additional costs to consider are:
- Reduction in takeoff thrust derate via lower flexible temperature
- Increase in engine wear as a result of higher EGT
- Increase in the use of braking devices at landing (brakes, thrust reversers, tires) due to heavier Landing Weight
- The extra fuel burn will result in an economical penalty due to possible emission taxation.

Note: *The fuel tankering method takes into account the cost for the transport of the tankered fuel.*

There are other operational aspects to consider when fuel tankering. The most common are risk of overweight landings are reduction in operation performance margins for short, hot or high elevation runways.

CALCULATION

Applicable to: ALL

The Fuel Price Ratio (FPR) is defined as the fuel price at the departure airport divided by the fuel price at the destination airport.
The Break-Even Fuel Price Ratio (BEFPR) introduces a limit fuel price ratio below which the fuel tankering becomes profitable from a fuel cost point of view.

When Fuel Price Ratio is below the BEFRP

- The advantage of the lower fuel price at departure compensates the additional fuel burn (the additional fuel burn is due to the additional fuel tankered)
- Fuel tankering maximizes the gain when as much fuel as possible is tankered
- The tankered fuel quantity is limited by:
  - Maximum fuel capacity
  - Structural or performance limited Maximum Takeoff Weight
  - Structural or performance limited Maximum Landing Weight
  - Fuel required for the next flight.

In case of Maximum Landing Weight limitation, the flight crew can limit the fuel tankered at their discretion in order to avoid possible overweight landing.
The following table shows the BEFPR versus the air distance of the first flight leg.
The table also indicates the additional fuel burn per 1 000 kg (1 000 lb) of extra fuel tankered. The total additional fuel burn must be added to the total trip fuel from the departure airport.

FUEL TANKERING TABLES

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Table assumptions are:

- ISA temperature
- Optimum flight level at Long Range cruise speed
- 30 min holding at 1 500 ft at Green Dot Speed

AIR DISTANCE (nm)	BREAK EVEN FUEL PRICE RATIO	FUEL BURN FOR 1000 kg OF FUEL TANKERED (kg)

2 500	No gain		No gain	

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

DATA :	Air distance	=	1 000 nm
	Fuel price at departure airport	=	830 $ / 1 000 kg (377 $ / 1 000 lb)
	Fuel price at destination airport	=	1000 $ / 1 000 kg (454 $ / 1 000 lb)

1. From the relation between fuel price at departure and fuel price at destination
   Current fuel price ratio = 0.83
2. Enter the Fuel Tankering table (*Refer to PER-FPL-FLP-FTK FUEL TANKERING TABLES*)
   For the defined air distance the BEFPR is 0.923, which is more than the current fuel price ratio.
   The fuel tankering is profitable.
   To determine the BEFPR, the interpolation of the table values is permitted.
   If the user wants to avoid interpolation, select the next longer air distance. This will provide a conservative value for BEFPR.
3. Determine total fuel quantity as maximum possible fuel limited by the following constraints:
   - Total fuel is less than maximum fuel tank capacity
   - TOW with fuel tankering is less than structural or performance limited maximum takeoff weight
   - LW with fuel tankering is less than structural or performance limited maximum landing weight
   - Tankered fuel is less than the trip fuel for the return flight plus total extra fuel burn.
4. Enter the table and read the fuel burn per 1 000 kg (1 000 lb) of extra fuel tankered.
   Every 1 000 kg (1000 lb) of extra fuel tankered causes an extra fuel burn of 77 kg (77 lb). Multiply this value by the amount of fuel tankered.
5. Trip fuel with fuel tankering = Trip fuel without fuel tankering + Extra fuel burn

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

DATA : Air distance = 1 000 nm
Fuel price at departure airport = 830 $ / 1 000 kg (377 $ / 1 000 lb)
Fuel price at destination airport = 1000 $ / 1 000 kg (454 $ / 1 000 lb)

1. From the relation between fuel price at departure and fuel price at destination
   Current fuel price ratio = 0.83
2. Enter the Fuel Tankering table (*Refer to PER-FPL-FLP-FTK FUEL TANKERING TABLES*)
   For the defined air distance the BEFPR is 0.934, which is more than the current fuel price ratio.
   The fuel tankering is profitable.
   To determine the BEFPR, the interpolation of the table values is permitted.
   If the user wants to avoid interpolation, select the next longer air distance. This will provide a conservative value for BEFPR.
3. Determine total fuel quantity as maximum possible fuel limited by the following constraints:
   - Total fuel is less than maximum fuel tank capacity
   - TOW with fuel tankering is less than structural or performance limited maximum takeoff weight
   - LW with fuel tankering is less than structural or performance limited maximum landing weight
   - Tankered fuel is less than the trip fuel for the return flight plus total extra fuel burn.
4. Enter the table and read the fuel burn per 1 000 kg (1 000 lb) of extra fuel tankered.
   Every 1 000 kg (1000 lb) of extra fuel tankered causes an extra fuel burn of 66 kg (66 lb). Multiply this value by the amount of fuel tankered.
5. Trip fuel with fuel tankering = Trip fuel without fuel tankering + Extra fuel burn

Applicable to: ALL

Climb tables are established at MAX CLIMB THRUST with air conditioning in normal mode and anti ice OFF.

The climb speed profile is :

- 250 kt from 1 500 ft up to FL 100
- acceleration from 250 kt to 300 kt
- climb at 300 kt then M .78 up to selected altitude.

All charts are established with a center of gravity corresponding to 33 %.

DEFINITIONS

Applicable to: ALL

- Optimum altitude : the altitude at which the airplane covers the maximum distance per kilogram (pound) of fuel (best specific range). It depends on the actual weight and the deviation from ISA.
- Maximum altitude is defined as the lower of :
  - maximum altitude at maximum cruise thrust in level flight and
  - maximum altitude at maximum climb thrust with 300 ft/min vertical speed.

Note: *Definition of the maximum altitude in the FMGC is different (Refer to DSC-22_20-50-10 MCDU).*

CRUISE LEVEL CHARTS GENERAL

Applicable to: ALL

These charts have been established for a center of gravity at 33 % MAC.
Maximum and optimum altitudes are given for different temperatures at long range speed and M 0.78.

Note: *The n = 1.3 g (n = 1.4 g) curve indicates the buffet margin.*

OPTIMUM WEIGHT FOR 4000 FEET STEP CLIMB

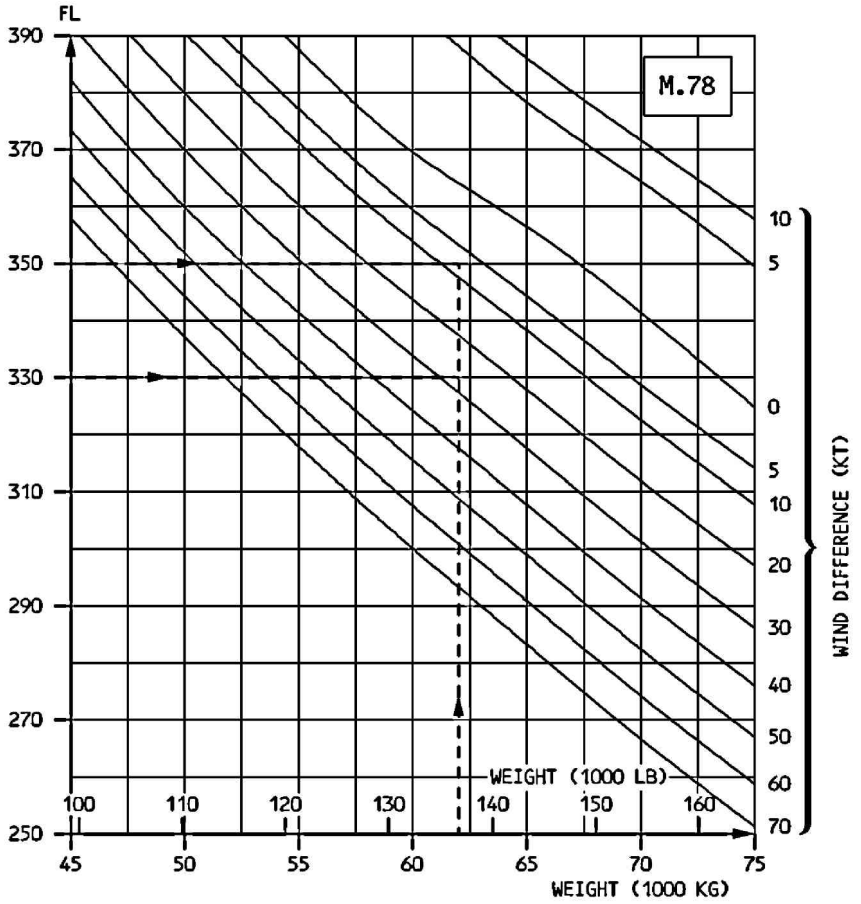
WIND ALTITUDE TRADE FOR CONSTANT SPECIFIC RANGE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR



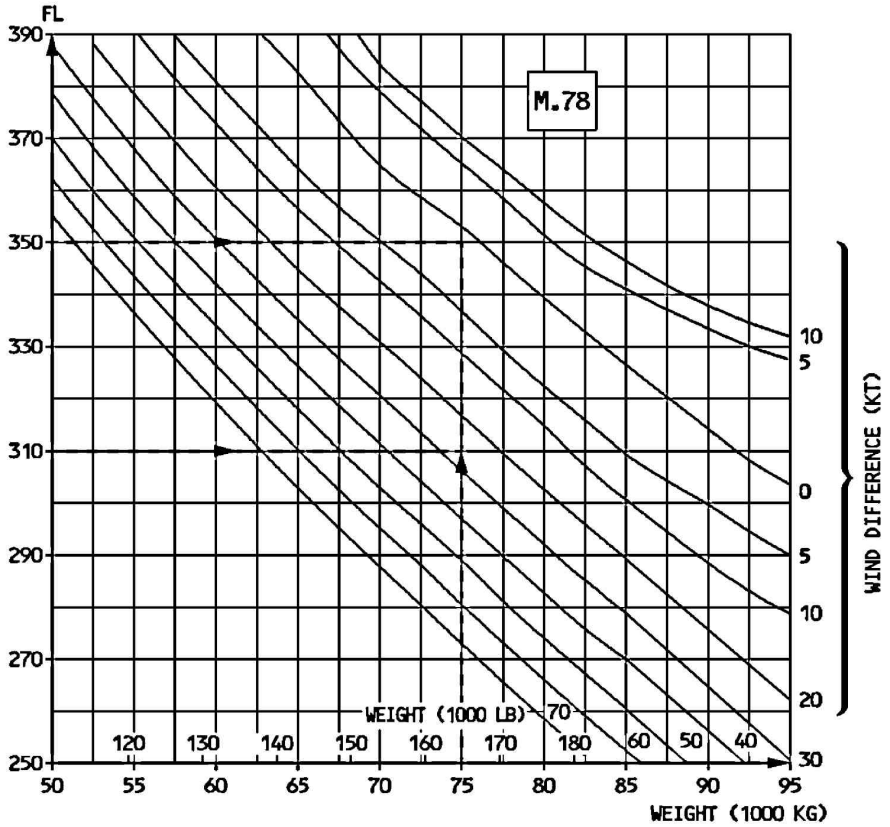
GIVEN : Weight : 62 000 kg (136 700 lb)
Wind at FL 350 : 10 kt head

FIND : Minimum wind difference to descend to FL 330 : (27 - 7) = 20 kt

RESULTS : Descent to FL 330 may be considered provided the tail wind at this altitude is more than (20 - 10) = 10 kt.

WIND ALTITUDE TRADE FOR CONSTANT SPECIFIC RANGE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI



GIVEN : Weight : 75 000 kg (165 300 lb)
Wind at FL 350 : 10 kt head

FIND : Minimum wind difference to descend to FL 310 : (27 - 2) = 25 kt

RESULTS : Descent to FL 310 may be considered provided the tail wind at this altitude is more than (25 - 10) = 15 kt.

Intentionally left blank

OPTIMUM ALTITUDE ON SHORT STAGE

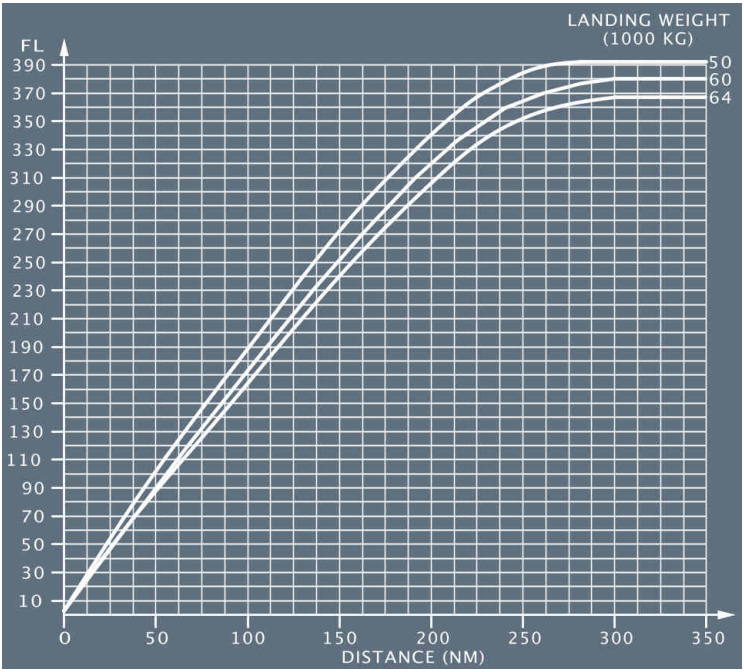
Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

According to the air distance (from brake release point to landing), the cruise flight level is limited by the distance required to perform climb and descent. The graph determines the optimum altitude.

It includes the following profiles:
- Takeoff
- Climb: 250 kt/300 kt/M .78
- Long range cruise (during at least 5 min)
- Descent: M .78/300 kt/250 kt
- Approach and landing

and it is established for:
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

ALTITUDE - OPTIMUM ALTITUDE ON SHORT STAGE



OPTIMUM ALTITUDE ON SHORT STAGE

GENERAL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to land.

These tables are established for:

- Cruise Mach number: M 0.78/LR
- Descent profile: M 0.78/300 kt/250 kt
- Approach and landing: 120 kg or 270 lb -6 min IMC
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk "*" means that a step climb of 4 000 ft has been made to reach the corresponding flight level.*

2. The flight level shown on the top of each column is the final flight level.

3. For each degree celsius above ISA apply a fuel correction of
0.005 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM)
or 0.011 (lb/°C/NM) x ΔISA (°C) x Air Distance (NM)

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to land.

These tables are established for:
- Cruise Mach number: M 0.78/LR
- Descent profile: M 0.78/300 kt/250 kt
- Approach and landing: 140 kg or 310 lb -6 min IMC
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk "*" means that a step climb of 4 000 ft has been made to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree celsius above ISA apply a fuel correction of
0.005 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM)
or 0.011 (lb/°C/NM) x ΔISA (°C) x Air Distance (NM)

CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT

Applicable to: ALL

The in cruise quick check tables are based on a reference initial weight.
The fuel consumption must be corrected when the actual weight is different from the reference initial weight.
If it is lower (or greater) than the reference weight, subtract (or add) the value given in the correction part of the table per 1 000 kg or 1 000 lb below (or above) the reference weight.

Intentionally left blank

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

In-cruise quick check with cruise at M .78
FL 370

Actual cruise weight : 55 000 kg

Remaining ground distance : 800 nm
ISA +10

Average wind during flight : -40 kt (head wind)

- Evaluation of air distance to be covered
  - Using the "Ground Distance/Air Distance" conversion table (*Refer to PER-OPD-CON-AEO M.78*), the corresponding air distance is : 880 nm
- Determination of the fuel consumption and time for the reference initial weight in cruise.
  - Enter table (*Refer to PER-CRZ-ICQ-40 IN CRUISE QUICK CHECK M.78*) with an air distance of 880 nm and FL 370 for ISA.
    Fuel consumption : 3 941 kg
    Time needed : 2 h 08 min
- Correction due to real in cruise weight of 55 000 kg
  - Δfuel consumption : -50 kg per 1 000 kg below reference
  - Δfuel : -50 ×(60 - 55) = - 250 kg
- Temperature correction :
  - Δfuel consumption : +0.005 kg per 1 °above ISA and per 1 nm Air distance
  - Δfuel : +0.005 ×10 ×880 = 44 kg

RESULT

Fuel : 3 941 - 250 + 44 = 3 735 kg

Time : 2 h 08 min

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

In-cruise quick check with cruise at M .78
FL 370

Actual cruise weight : 60 000 kg

Remaining ground distance : 800 nm
ISA +10

Average wind during flight : -40 kt (head wind)

- Evaluation of air distance to be covered
  - Using the "Ground Distance/Air Distance" conversion table (*Refer to PER-OPD-CON-AEO M.78*), the corresponding air distance is : 880 nm
- Determination of the fuel consumption and time for the reference initial weight in cruise.
  - Enter table (*Refer to PER-CRZ-ICQ-40 IN CRUISE QUICK CHECK M.78*) with an air distance of 880 nm and FL 370 for ISA.
    Fuel consumption : 4 344 kg
    Time needed : 2 h 07 min
- Correction due to real in cruise weight of 60 000 kg
  - Δfuel consumption : -50 kg per 1 000 kg below reference
  - Δfuel : -50 ×(65 - 60) = - 250 kg
- Temperature correction :
  - Δfuel consumption : +0.005 kg per 1 °above ISA and per 1 nm Air distance
  - Δfuel : +0.005 ×10 ×880 = 44 kg

RESULT

Fuel : 4 344 - 250 + 44 = 4 138 kg

Time : 2 h 07 min

CONF 1 - S SPEED C
CONF 1 - 170KT ..... D

Intentionally left blank

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Holding tables contain information about the total fuel flow that allows the flight crew to plan holding and reserve fuel requirements.

They are established for flight in a race track holding pattern for two different configurations:

- Clean configuration at 210 kt and green dot speed
- Configuration 1 at 170 kt and S speed.

Green dot speed in clean configuration and S in CONF 1 are speeds between the minimum fuel speed and the minimum drag speed.
These charts are established with air conditioning in normal mode and the center of gravity at 33 %.

GENERAL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Holding tables contain information about the total fuel flow that allows the flight crew to plan holding and reserve fuel requirements.

They are established for flight in a race track holding pattern for two different configurations:

- Clean configuration at 210 kt and green dot speed + 20 kt
- Configuration 1 at 170 kt and S speed.

Green dot speed in clean configuration and S in CONF 1 are speeds between the minimum fuel speed and the minimum drag speed.
These charts are established with air conditioning in normal mode and the center of gravity at 33 %.

In the go around configuration corresponding to the all engine procedure, the minimum steady gradient one engine inoperative required by the regulations is 2.1 % at a speed not exceeding 1.4 Vs. This requirement is also called approach climb performance by regulations.
The following tables allow to determine the go around limiting weight which satisfies the required gradient with the certified go around configurations 3 and 2.
The required gradient of 2.1 % is considered at the airport reference altitude. The power setting is "GO AROUND" thrust with the air conditioning ON. The speed is 1.23 Vs of the specified configuration. For the occasional cases where approach climb performance is found restrictive, a correction is given for an increased speed, up to 1.4 Vs.

Note: *Landing climb performance (2 engines running) is never limiting.*

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

In the go around configuration corresponding to the all engine procedure, the minimum steady gradient one engine inoperative required by the regulations is 2.1 % at a speed not exceeding 1.4 Vs. This requirement is also called approach climb performance by regulations.
The following graph allow to determine the go around limiting weight which satisfies the required gradient with the certified go around configurations 3 and 2.
The required gradient of 2.1 % is considered at the airport reference altitude. The power setting is "GO AROUND" thrust with the air conditioning ON. The speed is 1.23 Vs of the specified configuration. For the occasional cases where approach climb performance is found restrictive, a correction is given for an increased speed, up to 1.4 Vs.

Note: *Landing climb performance (2 engines running) is never limiting.*

PROCEDURE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

According to airport pressure altitude and temperature determine if the slats/flaps setting must be restricted as a function of the landing weight, in order to meet the go around gradient requirement of 2.1 %.

Establish the final approach configuration with one more step of flaps. If the approach is interrupted, retract the flaps by one step during the go-around.

In case of category II approach, JAR-OPS requires a regulatory approach climb gradient of 2.5 % to be maintained.

Use the tables for CAT II approach to determine the maximum approach climb limiting weight according to airport pressure altitude and temperature.

Note:

1. *If circumstances dictate, landing may be made at a weight corresponding to the maximum structural takeoff weight. (Refer to PRO-ABN-80 OVERWEIGHT LANDING).*
2. *When icing conditions are predicted during the flight and TAT is 10 °C or below and there is an evidence of significant ice accretion, to take into account ice formation on the non heated structure :*
   - *decrease the approach climb limiting weight by 4.5 %.*
   - *in CONF FULL, the approach speed must not be lower than VREF +5 kt and the landing distance must be multiplied by 1.1.*
     or
     in CONF 3, the approach speed must not be lower than VLS +10 kt and the landing distance must be multiplied by 1.15.
3. *In the following tables corrections for anti ice are only valid for OAT lower than 10 °C.*

PROCEDURE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

According to airport pressure altitude and temperature determine if the slats/flaps setting must be restricted as a function of the landing weight, in order to meet the go around gradient requirement of 2.1 %.

Establish the final approach configuration with one more step of flaps. If the approach is interrupted, retract the flaps by one step during the go-around.

GENERAL

Applicable to: ALL

ACTUAL LANDING DISTANCE

The actual landing distance is the distance measured between a point 50 ft above the runway threshold and the point where the complete stop of the aircraft is achieved.

It assumes that:

- the approach speed is:
  - VLS (1.23 VS of the configuration) for manual landing
  - VLS + 5 kt for CAT II/CAT III automatic landing.
- the pilot applies maximum braking and the antiskid system is operating.
- the ground spoilers are operating.

It does not consider the use of reverse thrust.

REQUIRED LANDING DISTANCE

MANUAL LANDING

Regulation defines the required landing distance as the actual landing distance divided by 0.6, assuming the surface is dry.
If the surface is wet, the required landing distance must be at least 115 % of that for a dry surface.
For EU-OPS operators, if the surface is contaminated, the required landing distance must be at least the greater of the required landing distance on wet runway (see previous paragraph) and 115 % of the landing distance determined in accordance with approved contaminated landing distance data.
For A319 operations in SANTOS-DUMONT, the required manual landing distance on wet runway is equal to the required manual landing distance on dry runway, until embodiment of BSCU standard 8.

AUTOMATIC LANDING

Regulation (CS.AWO 142) defines the required landing distance for automatic landing as the actual landing distance in automatic landing multiplied by 1.15. This distance must be retained for automatic landing whenever it is greater than the required landing distance in manual mode.

DISPATCH

Applicable to: ALL

The pilot must check before departure that the available runway length at destination is at least equal to the required landing distance for the forecasted landing weight.
In case of aircraft system failure affecting landing distance known before the dispatch, the available runway length must be at least equal to the required landing distance with failure, i.e. the required landing distance without failure multiplied by the coefficient given in the Flight Manual or the MMEL.

USE OF THE AUTOBRAKE SYSTEM

Applicable to: ALL

The autobrake system is designed to help the pilot in case of :
- aborted takeoff or
- landing on short runways or
- operation with low visibility weather conditions

Furthermore, it ensures a straight roll-out and optimizes the landing distance on contaminated runways provided the contamination is evenly distributed.

The following tables cover :
- dry runway
- wet runway
- runway covered with water, slush or compacted snow
- icy runway

At landing, select the braking mode according to :
- runway length
- configuration
- runway condition

A correction is necessary :
- if landing is not performed at sea level
- if reverse thrust is used
- in windy conditions
- for forward CG (A320-200 only)

GENERAL

Applicable to: ALL

This section presents the recommendations of Airbus Industrie for operations from wet runways or from runways which are covered with contaminants such as standing water, slush or snow.

Intentionally left blank

DEFINITIONS

Applicable to: ALL

DAMP : A runway is damp when the surface is not dry, but when the water on it does not give it a shiny appearance.

WET : A runway is considered as wet when the surface has a shiny appearance due to a thin layer of water. When this layer does not exceed 3 mm depth, there is no substantial risk of hydroplaning.

STANDING WATER is caused by heavy rainfall and/or insufficient runway drainage with a depth of more than 3 mm.

SLUSH : is water saturated with snow which spatters when stepping firmly on it. It is encountered at temperatures around 5 °C and its density is approximately 0.85 kg/l (7.1 lb/US Gal).

WET SNOW : is a condition where, if compacted by hand, snow will stick together and tend to form a snowball. Its density is approximately 0.4 kg/l (3.35 lb/US Gal).

DRY SNOW : is a condition where snow can be blown if loose, or if compacted by hand, will fall apart again upon release. Its density is approximately 0.2 kg/l (1.7 lb/US Gal).

COMPACTED SNOW is a condition where snow has been compressed (a typical friction coefficient is 0.2).

ICY : is a condition where the friction coefficient is 0.05 or below.

The performance given in this chapter has been divided into two categories which are determined by the depth of the contaminant. For each of these categories an equivalent depth of contaminant has been defined for which the performance deterioration is the same.

1. WET RUNWAY and EQUIVALENT

Equivalent of a wet runway is a runway covered with or less than:
- 3 mm (0.12 in) slush
- 3 mm (0.12 in) water
- 4 mm (0.16 in) wet snow
- 15 mm (0.59 in) dry snow

2. CONTAMINATED RUNWAY

An equivalence between depth of slush and snow has been defined:
- 12.7 mm (1/2 inch) wet snow is equivalent to 6.3 mm (1/4 inch) slush
- 25.4 mm (1 in) wet snow is equivalent to 12.7 mm (1/2 inch) slush
- 50.8 mm (2 in) dry snow is equivalent to 6.3 mm (1/4 inch) slush
- 101.6 mm (4 in) dry snow is equivalent to 12.7 mm (1/2 inch) slush.

MANUAL LANDING ON DRY RUNWAY

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

REQUIRED LANDING DISTANCE (METERS)										
WEIGHT (1 000 KG)	**58**	**62**	**66**	**70**	**74**	**78**	**82**	**86**	**90**	**94**
CONF 3	1 430	1 490	1 560	1 630	1 700	1 780	1 910	2 280	2 440	2 610
CONF FULL	1 360	1 420	1 480	1 550	1 610	1 690	1 800	2 140	2 300	2 450

CORRECTIONS ON LANDING DISTANCES

Wind : per 10 kt tailwind add 16 %
No correction for headwind due to wind correction on approach speed.

Airport elevation : per 1 000 ft above sea level add 3 %.

MANUAL LANDING ON DRY RUNWAY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

REQUIRED LANDING DISTANCE (METERS)									
WEIGHT (1 000 KG)	**46**	**50**	**54**	**58**	**62**	**66**	**70**	**74**	**78**
CONF 3	1 210	1 270	1 330	1 390	1 470	1 610	1 770	1 930	2 070
CONF FULL	1 150	1 210	1 260	1 320	1 380	1 480	1 630	1 780	1 910

CORRECTIONS ON LANDING DISTANCES

Wind : per 10 kt tailwind add 18 %
No correction for headwind due to wind correction on approach speed.

Airport elevation : per 1 000 ft above sea level add 3 %.

Forward CG : add 2 %.

Intentionally left blank

AUTOMATIC LANDING ON DRY RUNWAY

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

Determine the corrected required landing distance for manual landing from the data above.

The required landing distance for automatic landing is equal to the corrected required landing distance for manual landing except in the following cases:

- In case of landing in CONF 3 with landing weight equal to or less than 60 000 kg and with headwind at or above 20 kt, it is equal to the corrected required landing distance for manual landing increased by 60 m.
- In case of landing in CONF FULL with landing weight equal to or less than 60 000 kg and with headwind at or above 20 kt, it is equal to the corrected required landing distance for manual landing increased by 80 m.

AUTOMATIC LANDING ON DRY RUNWAY

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

Determine the corrected required landing distance for manual landing from the data above.

The required landing distance for automatic landing is equal to the corrected required landing distance for manual landing except in the following case:

- In case of landing in CONF 3 with landing weight equal to or less than 65 000 kg and with headwind at or above 10 kt, it is equal to the corrected required landing distance for manual landing increased by 90 m.
- In case of landing in CONF FULL with landing weight equal to or less than 45 000 kg and with headwind at or above 30 kt, it is equal to the corrected required landing distance for manual landing increased by 10 m.

Intentionally left blank

FAILURE IN FLIGHT

Applicable to: ALL

In case of an aircraft system failure occurring in flight and affecting the landing performance, the runway length to be considered for landing is the actual landing distance without failure multiplied by the landing distance coefficient associated with the failure. The coefficients are given in *Refer to PRO-ABN-80 LDG CONF/APPR SPD/LDG DIST Table - DRY RWY - 24 - ELEC* and in the QRH. The concept of required landing distance no longer applies.

RECOMMENDATIONS

For most cases of abnormal landing configuration, the increased actual landing distance does not exceed the required runway length for landing in normal configuration.

However, the addition of several of these factors can very quickly lead to an overrun. Special notice should be taken of the runway condition. A slippery runway is the most common reason for overrun at landing. The combination of a slippery runway and a factor such as tailwind or an increase in approach speed should be avoided.

As far as possible, avoid the combination of any failure affecting the braking capability of the aircraft (spoilers, reversers) with landing on a contaminated runway, or prepare for it carefully by checking the available runway length against the forecasted landing distance.

During a visual approach, use all means of monitoring the flight path; use the ILS together with available visual aids such as VASI or PAPI. Monitor the approach speed along with the wind and ground speed, especially during final approach.

Intentionally left blank

CONFIGURATION 3

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

INTRODUCTION

Applicable to: ALL

This chapter provides the single engine performance data to be used for the conduct and monitoring of the flight following an engine failure.
The diversion strategy (descent and cruise speed schedules) shall be selected, and specified in the operator's routes specifications, as a function of the prevailing operational factors (e.g. obstacles clearance requirements and/or ETOPS operation).

FLIGHT PREPARATION

Applicable to: ALL

In readiness for a possible engine failure occurring during the flight, any flight shall be planned so as to comply with any of the following requirements, as applicable :

- obstacle clearance,
- oxygen,
- maximum diversion distance (ETOPS operation).

The following FCOM sections provide flight preparation and fuel planning information :

- *Refer to PER-FPL-GEN-INT GENERAL*, for Standard Fuel Planning,
- *Refer to PRO-SPO-40-10 General*, for Extended Range Operation (ETOPS) and associated fuel requirements.

STRATEGY

Applicable to: ALL

Depending on the prevailing operational constraints, the most appropriate diversion strategy shall be selected, out of the following options:

	STANDARD STRATEGY	OBSTACLE STRATEGY	FIXED SPEED STRATEGIES	
			320 kt	VMO
DESCENT TO CEILING	• M .78/300 kt • MCT	• Green Dot Speed • MCT	• M .78/320 kt • MCT	• M .80/350 kt • MCT
CRUISE	LR ceiling LR speed	- Obstacle not cleared: Maintain Green Dot Speed at MCT - Obstacle cleared : Revert to standard strategy	FL per *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - One Engine Out - Cruise at 320kt* MCT/320 kt	FL per *Refer to PRO-SPO-40-60 ETOPS Fuel from Critical Point to Landing - One Engine Out - Cruise at 350kt* MCT/350 kt
DESCENT TO LANDING	IDLE/M .78/300 kt/250 kt			
Approx increase in fuel consumption compared with both engines operative	+33 %			

For ETOPS operations, any of the above diversion strategies can be used provided that the selected strategy and speed schedule is used in:

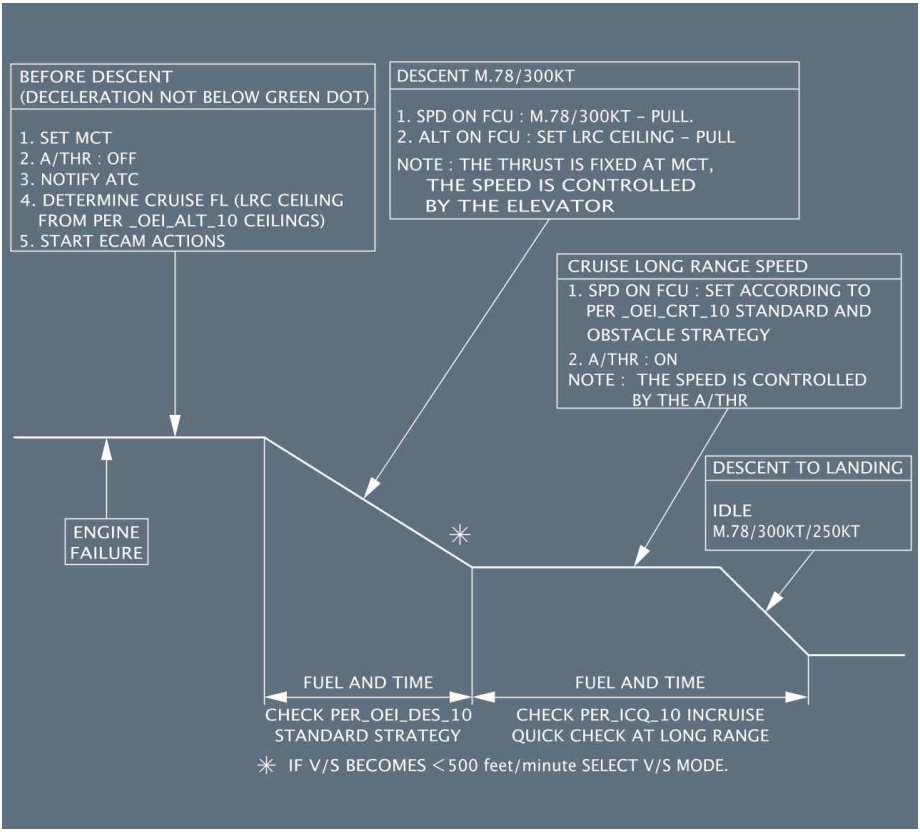
- establishing the area of operation (maximum diversion distance), *Refer to PRO-SPO-40-60 General*,
- calculating the diversion fuel requirements for the single engine ETOPS critical scenario, *Refer to PRO-SPO-40-30 ETOPS Fuel Scenarios*,
- demonstrating the applicable obstacle clearance requirements (net flight path and net ceiling).

During the diversion, the flight crew is expected to use the planned speed schedule.
However, based on the evaluation of the actual situation, the pilot in command has the authority to deviate from this planned one engine inoperative speed.

PROCEDURE

Applicable to: ALL

Unless a specific procedure has been established before dispatch (ETOPS, mountainous areas) the recommended procedure is as follows :



EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

GIVEN:

GW at engine failure = 70 000 kg
FL at engine failure = 310
Temperature = ISA
Distance to diversion airport = 560 nm
No wind

FIND:

LRC ceiling : (*Refer to PER-OEI-ALT-10 GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS*) FL 182

Descent to cruise level: (FL 180) *Refer to PER-OEI-DES-10 DESCENT - M.78/300KT*
Distance = 235 - 98 = 137 nm
Fuel = 1 248 - 567 = 681 kg
Time = 35.6 - 16.0 = 19.6 min

Cruise at long range speed (FL 180) to landing.
(Weight = 70 000 - 681 = 69 319 kg: Distance = 560 - 137 = 423 nm)
Determine on (*Refer to PER-OEI-ICQ-10 IN CRUISE QUICK CHECK LONG RANGE*) time and fuel consumption at ISA conditions and for a reference weight of 55 000 kg. Interpolate the remaining air distance of 423 nm at FL 180.

Fuel : 2 435 kg

Time : 1 h 24 min

Correction due to actual in-cruise weight

ΔFuel = +19 kg per 1 000 kg above reference weight

ΔFuel = +19 kg $\times$(69.3 – 55) ~ 280 kg

RESULT:

Total Fuel = 681 + 2 435 + 280 = 3 396 kg

Time = 1 h 24 min + 20 min = 1 h 44 min

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

GIVEN

GW at engine failure	=	80 000 kg
FL at engine failure	=	310
Temperature	=	ISA
Distance to diversion airport No wind	=	550 nm

FIND

LRC ceiling : (*Refer to PER-OEI-ALT-10 GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS*) FL 162

Descent to cruise level : (FL 160) *Refer to PER-OEI-DES-10 DESCENT - M.78/300KT*
Distance = 226 - 72 = 154 nm
Fuel = 1 354 - 482 = 872 kg
Time = 34.2 - 12 = 22.2 min

Cruise at long range speed (FL 160) to landing :
(Weight = 80 000 - 872 = 79 128 kg : Distance = 550 - 154 = 396 nm)
Determine on (*Refer to PER-OEI-ICQ-10 IN CRUISE QUICK CHECK LONG RANGE*) time and fuel consumption at ISA conditions for a reference weight of 60 000 kg. Interpolate the remaining air distance of 396 nm at FL 160.

Fuel : 2 622 kg

Time : 1 h 20 min

Correction due to actual in-cruise weight

ΔFuel = +22 kg per 1 000 kg above reference weight

ΔFuel = +22 kg $\times$(79.1 – 60) ~ 420 kg

RESULT

Total Fuel = 872 + 2 622 + 420 = 3 914 kg

Time = 1 h 20 min + 22 min = 1 h 42 min

Intentionally left blank

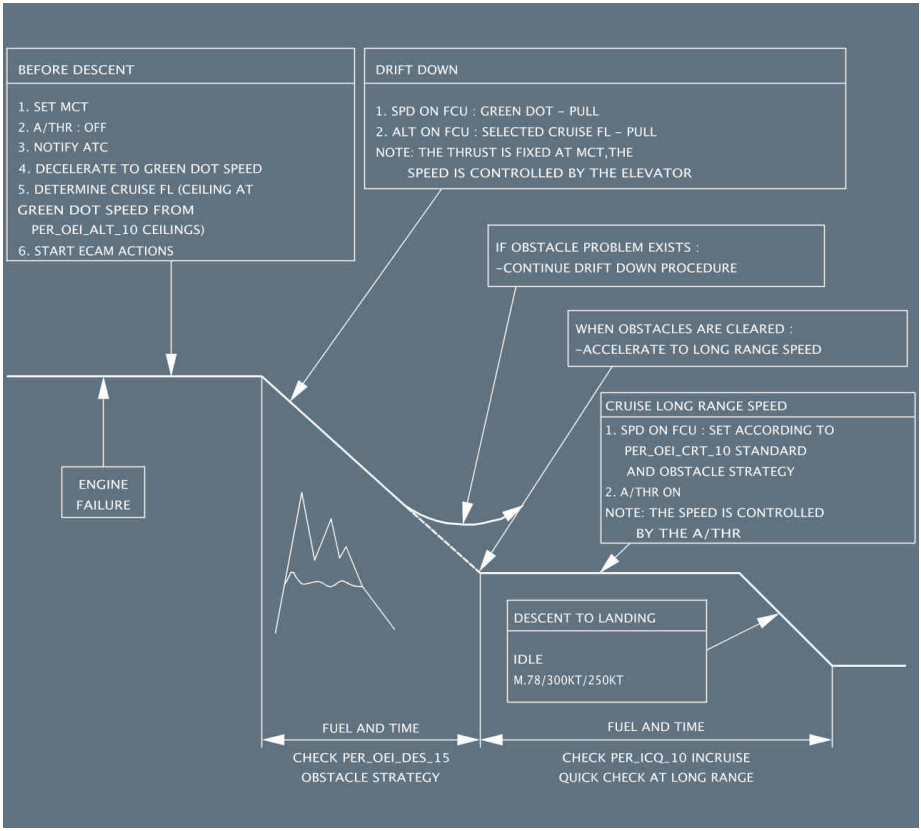
PROCEDURE

Applicable to: ALL

In order to maintain the highest possible level, the drift down procedure must be adopted.
This requires maximum continuous thrust on the remaining engine at green dot speed.

- **If, having reached drift down ceiling altitude, an obstacle problem remains, the drift down procedure must be maintained so as to fly an ascending cruise profile.**
- **If, after drift down, no obstacle problem remains, the speed should be allowed to increase to long range speed and maintained. The subsequent cruise should be made using either the long range speed by adjusting it as a function of aircraft weight or by maintaining the initial cruise speed.**

Note: Due to the fact that the long range speed is higher than the green dot speed, the cruise will be made at an altitude lower than the drift down ceiling.



BEFORE DESCENT
1. SET MCT
2. A/THR : OFF
3. NOTIFY ATC
4. DECELERATE TO GREEN DOT SPEED
5. DETERMINE CRUISE FL (CEILING AT GREEN DOT SPEED FROM PER_OEI_ALT_10 CEILINGS)
6. START ECAM ACTIONS
DRIFT DOWN
1. SPD ON FCU : GREEN DOT – PULL
2. ALT ON FCU : SELECTED CRUISE FL – PULL
NOTE: THE THRUST IS FIXED AT MCT,THE SPEED IS CONTROLLED BY THE ELEVATOR
IF OBSTACLE PROBLEM EXISTS :
–CONTINUE DRIFT DOWN PROCEDURE
WHEN OBSTACLES ARE CLEARED :
–ACCELERATE TO LONG RANGE SPEED
CRUISE LONG RANGE SPEED
1. SPD ON FCU : SET ACCORDING TO PER_OEI_CRT_10 STANDARD AND OBSTACLE STRATEGY
2. A/THR ON
NOTE: THE SPEED IS CONTROLLED BY THE A/THR
ENGINE FAILURE

EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

GIVEN

GW at engine failure = 62 000 kg

FL at engine failure = 350

Temperature = ISA

Distance to destination airport = 1 500 nm
No wind

FIND

Level off (drift down ceiling) (*Refer to PER-OEI-DES-15 GROSS FLIGHT PATH DESCENT AT GREEN DOT SPEED - ISA*) : 24 300 ft

Distance : 338 nm

Fuel : 1 800 kg

Time : 1 h 04 min

LRC ceiling : (*Refer to PER-OEI-ALT-10 GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS*) : FL 202

Cruise at long range speed (FL 200) to landing
(weight = 62 000 - 1 800 = 60 200 kg : Distance = 1 500 - 338 = 1 162 nm)
Determine on (*Refer to PER-OEI-ICQ-10 IN CRUISE QUICK CHECK LONG RANGE*) time and fuel consumption at ISA conditions for a reference weight of 55 000 kg. Interpolate the remaining air distance of 1 162 nm at FL 200.

Fuel : 6 503 kg

Time : 3 h 34 min

Correction due to actual in-cruise weight

ΔFuel = +58 kg per 1 000 kg above reference weight

ΔFuel = +58 kg $\times$(60.2 – 55) ~ 302 kg

RESULT

Total Fuel = 6 503 + 302 + 1 800 = 8 605 kg

Time = 3 h 34 min + 1 h 04 min = 4 h 38 min

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

GIVEN:

GW at engine failure = 70 000 kg
FL at engine failure = 350
Temperature = ISA
Distance to destination airport = 1 500 nm
No wind

FIND:

Level off (drift down ceiling) (*Refer to PER-OEI-DES-15 GROSS FLIGHT PATH DESCENT AT GREEN DOT SPEED - ISA*) : 22 900 ft
Distance : 376 nm
Fuel : 2 400 kg
Time : 1 h 10 min
LRC ceiling: (*Refer to PER-OEI-ALT-10 GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS*) : FL 203

Cruise at long range speed (FL 200) to landing
(weight = 70 000 - 2 400 = 67 600 kg: Distance = 1 500 - 376 = 1 124 nm)
Determine on (*Refer to PER-OEI-ICQ-10 IN CRUISE QUICK CHECK LONG RANGE*) time and fuel consumption at ISA conditions for a reference weight of 60 000 kg. Interpolate the remaining air distance of 1 124 nm at FL 200.

Fuel : 6 992 kg
Time : 3 h 27 min

Correction due to actual in-cruise weight

ΔFuel = +68 kg per 1 000 kg above reference weight
ΔFuel = +68 kg ×(67.6 – 60) ~ 517 kg

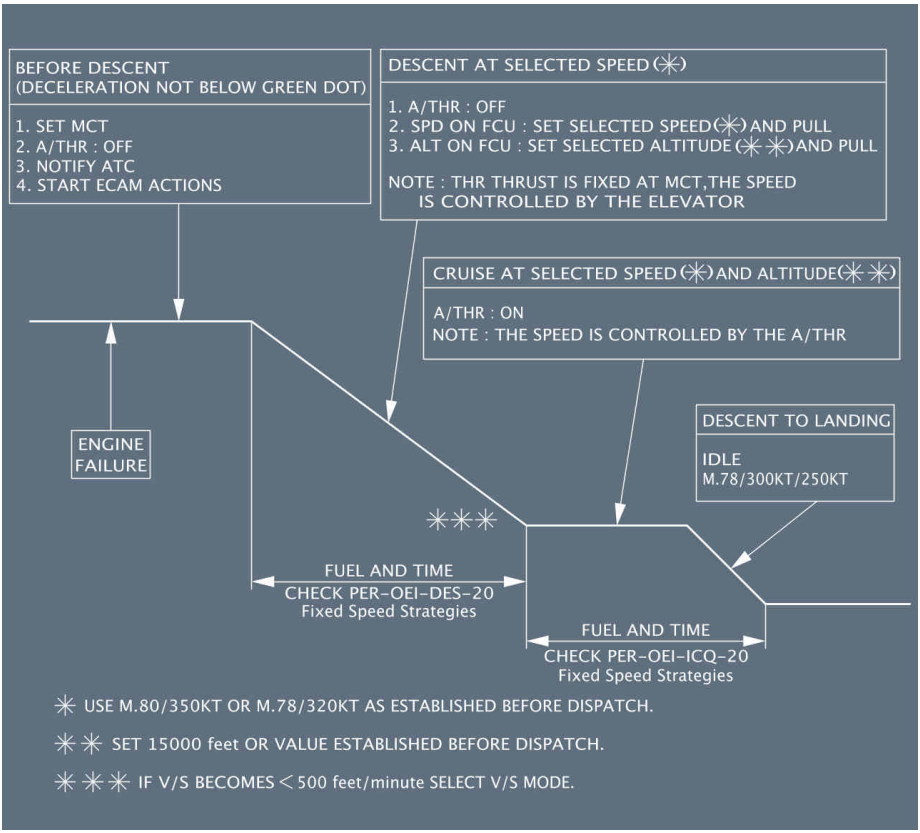
RESULT:

Total Fuel = 6 992 + 517 + 2 400 = 9 909 kg
Time = 3 h 27 min + 1 h 10 min = 4 h 37 min

PROCEDURE

Applicable to: ALL

This section provides single engine performance data for two fixed speed diversion strategies (fixed descent and cruise speed schedules) recommended for ETOPS operation, provided that the requirements set forth, *Refer to PER-OEI-GEN-05 INTRODUCTION*, are complied with.



EXAMPLE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

GIVEN :

GW at engine failure	=	70 000 kg
FL at engine failure	=	350
Temperature	=	ISA
Distance to diversion airport	=	500 nm
Speed selected before dispatch	=	350 kt
Cruise level for diversion Selected before dispatch	=	FL 180

FIND :

Descent to cruise level (*Refer to PER-OEI-DES-20 DESCENT - M.80/350KT*) : Distance = 199 - 106 = 93 nm
Fuel = 1 186 - 760 = 426 kg
Time = 26.9 - 15.1 = 11.8 min

Cruise

Weight = 70 000 - 426 = 69 574 kg

Distance = 500 - 93 = 407 nm

Determine (*Refer to PER-OEI-ICQ-20 IN CRUISE QUICK CHECK VMO*) time and fuel consumption at ISA conditions for a reference weight of 55 000 kg

Interpolate the remaining distance of 407 nm at FL 180

Fuel = 2 595 kg

Time = 1 h 12 min

Correction due to actual in-cruise weight : no correction here

RESULT :

Total Fuel = 2 595 + 426 = 3 021 kg

Time = 1 h 12 min + 12 min = 1 h 24 min

EXAMPLE

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

GIVEN :

GW at engine failure	=	75 000 kg
FL at engine failure	=	350
Temperature	=	ISA
Distance to diversion airport	=	500 nm
Speed selected before dispatch	=	350 kt
Cruise level for diversion Selected before dispatch	=	FL 180

FIND :

Descent to cruise level (*Refer to PER-OEI-DES-20 DESCENT - M.80/350KT*) : Distance = 194 - 102 = 92 nm
Fuel = 1 250 - 780 = 470 kg
Time = 26.2 - 14.5 = 11.7 min

Cruise

Weight = 75 000 - 470 = 74 530 kg

Distance = 500 - 92 = 408 nm

Determine (*Refer to PER-OEI-ICQ-20 IN CRUISE QUICK CHECK VMO*) time and fuel consumption at ISA conditions for a reference weight of 60 000 kg

Interpolate the remaining distance of 408 nm at FL 180

Fuel = 2 839 kg

Time = 1 h 11 min

Correction due to actual in-cruise weight

△Fuel = +3 kg per 1 000 kg above reference weight

△Fuel = +3 kg ×(74.5 – 60) ~ 44 kg

RESULT :

Total Fuel = 2 839 + 44 + 470 = 3 353 kg

Time = 1 h 11 min + 12 min = 1 h 23 min

Intentionally left blank

GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

		ISA	ISA+10	ISA+15	ISA+20
LONG RANGE	ENGINE ANTI ICE ON	-1300FT	-1300FT	-1400FT	-1400FT
	TOTAL ANTI ICE ON	-2800FT	-2800FT	-2800FT	-3000FT
GREEN DOT	ENGINE ANTI ICE ON	-1000FT	-1000FT	-1100FT	-1200FT
	TOTAL ANTI ICE ON	-2100FT	-2100FT	-2300FT	-2500FT

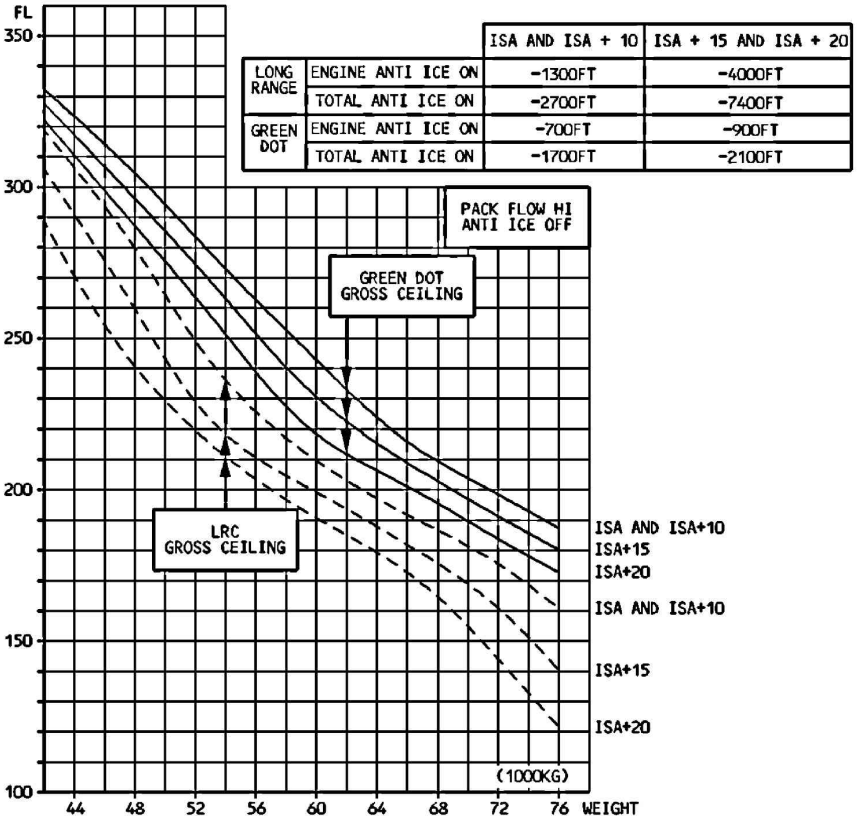
Note: *1. For weights above 85 000 kg, one engine ceilings at Long Range speed may be overestimated by FMS Legacy. In this case, ceiling values provided in the above graph should be retained.*

2. If severe icing conditions are encountered, ice formation may build up on non heated structure and therefore the ceiling will be reduced by 2 400 ft.

GROSS CEILINGS AT LONG RANGE AND GREEN DOT SPEEDS

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

		ISA AND ISA + 10	ISA + 15 AND ISA + 20
LONG RANGE	ENGINE ANTI ICE ON	-1300FT	-4000FT
	TOTAL ANTI ICE ON	-2700FT	-7400FT
GREEN DOT	ENGINE ANTI ICE ON	-700FT	-900FT
	TOTAL ANTI ICE ON	-1700FT	-2100FT



Note: If severe icing conditions are encountered, ice formation may build up on non heated structure and therefore the ceiling will be reduced by 2 000 ft.

NET CEILING AT GREEN DOT SPEED

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

To obtain the net ceiling at green dot speed, apply the following corrections to the gross ceiling at green dot speed:

	WEIGHT (1 000 kg)					
	52	**60**	**68**	**76**	**84**	**92**
≤ISA +10	-5 200 ft	-5 200 ft	-3 500 ft	-4 600 ft	-6 000 ft	-7 100 ft
ISA +20	-5 500 ft	-3 800 ft	-4 300 ft	-6 400 ft	-7 200 ft	-8 300 ft

NET CEILING AT GREEN DOT SPEED

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

To obtain the net ceiling at green dot speed, apply the following corrections to the gross ceiling at green dot speed:

	WEIGHT (1 000 kg)							
	48	**52**	**56**	**60**	**64**	**68**	**72**	**76**
≤ISA +10	-4 500 ft	-4 700 ft	-4 700 ft	-4 000 ft	-3 300 ft	-3 300 ft	-3 700 ft	-4 600 ft

IN CRUISE QUICK CHECK AT LONG RANGE SPEED

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to landing, with one engine inoperative.

These tables are established for:
- Cruise Mach number : long range
- Descent profile : M .78/300 kt/250 kt
- Approach and landing : 120 kg or 270 lb - 6 min IMC
- ISA
- CG = 33 %
- Pack flow HI
- Anti ice OFF

Note: *1. In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA temperature apply a fuel correction of 0.015 (kg/°C/NM) x Δ ISA (°C) x air distance (NM) or 0.033 (lb/°C/NM) x ΔISA (°C) x air distance (NM).

IN CRUISE QUICK CHECK AT LONG RANGE SPEED

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to landing, with one engine inoperative.

These tables are established for :
- Cruise Mach number : long range
- Descent profile : M .78/250 kt/300 kt
- Approach and landing : 140 kg or 340 lb -6 min IMC
- ISA
- CG = 33 %
- Normal air conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk (*) means that a step climb of 4 000 ft must be flown to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA temperature apply a fuel correction of 0.015 (kg/°C/NM) x Δ ISA (°C) x air distance (NM) or 0.033 (lb/°C/NM) x ΔISA (°C) x air distance (NM).

CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT

Applicable to: ALL

The in cruise quick check tables are based on a reference initial weight.
A correction on the fuel consumption has to be made, when the actual initial weight is different from the reference initial weight.
If it is lower (or greater) than the reference weight, subtract (or add) the value given in the correction part of the table per 1 000 kg or 1 000 lb below (or above) the reference initial weight (*Refer to PER-OEI-GEN-20 EXAMPLE*).

IN CRUISE QUICK CHECK LONG RANGE

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

GENERAL

Applicable to: B-HSD, B-HSE, B-HSG, B-HSI, B-HSJ, B-HSK, B-HSL, B-HSM, B-HSN, B-HSO, B-HSP, B-HSQ, B-HSR

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to landing with one engine inoperative.

These tables are established for:
- Cruise speed: MCT/VMO, MCT/320 kt.
- Descent profile: M .78/300 kt/250 kt
- Approach and landing: 120 kg or 270 lb - 6 min IMC
- ISA
- CG = 33 %
- Pack flow HI
- Anti ice OFF

Note: *1. In the tables, the asterisk "*" means that a step climb of 4 000 ft has been made to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA apply a fuel correction of
0.015 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM)
or 0.033 (lb/°C/NM) x ΔISA (°C) x Air Distance (NM)

GENERAL

Applicable to: B-HTD, B-HTE, B-HTF, B-HTG, B-HTH, B-HTI

The following in cruise quick check tables allow the flight crew to determine the fuel consumption and the time required to cover a given air distance from any moment in cruise to landing with one engine inoperative.

These tables are established for :
- Cruise speed: MCT/VMO, MCT/320 kt.
- Descent profile: M .78/300 kt/250 kt
- Approach and landing: 140 kg or 310 lb –6 min IMC
- ISA
- CG = 33 %
- Normal Air Conditioning
- Anti ice OFF

Note: *1. In the tables, the asterisk "*" means that a step climb of 4 000 ft has been made to reach the corresponding flight level.*
2. The flight level shown on the top of each column is the final flight level.
3. For each degree Celsius above ISA apply a fuel correction of
0.015 (kg/°C/NM) x ΔISA (°C) x Air Distance (NM)
or 0.033 (lb/°C/NM) x ΔISA (°C) x Air Distance (NM)

CORRECTION FOR DEVIATION FROM REFERENCE WEIGHT

Applicable to: ALL

The in cruise quick check tables are based on a reference initial weight. The fuel consumption must be corrected when the actual weight is different from the reference initial weight.
If it is lower (or greater) than the reference weight, subtract (or add) the value given in the correction part of the table per 1 000 kg or 1 000 lb below (or above) the reference weight (*Refer to PER-OEI-GEN-20 EXAMPLE*).
